# FORGED FITTINGS *for light weight plus Reliability*

• For vital structural and operating parts, the industry is steel, and properly making use of precision forged parts of Alcoa Aluminum.

Forged parts are actually lighter, because of the higher strength, resistance, and shock-resisting qualities of the wrought metal. They provide greater homogeneity, greater continuity of uniform properties.

Advanced practices recently developed in Alcoa Aluminum engineers make these products available to the industry with still greater economy. This important development is one more step in the progress Alcoa Aluminum is making with and for the industry.

For details concerning forged parts, including forged pipe fittings, address ALUMINUM COMPANY OF AMERICA, 1802 Gulf Building, Pittsburgh, Pa.

**WRIGHT WHIRLWINDS POWER  
THE LOCKHEED ELECTRA TRANSPORTS**

Now  
IN OPERATION  
ON  
EASTERN AIR LINES  
and  
DELTA AIR LINES

Wright "Whirlwinds" were selected to power the fleets of new 10-passenger Lockheed Electra transports recently placed in service on Eastern Air Lines and Delta Air Lines.

The swift, 210-mile-per-hour Electra is the newest member of the famous Lockheed line of airplanes. Powered by two economical Wright "Whirlwinds," each developing 450 h.p. for take-off, the Electra is one of the world's fastest and most luxuriously furnished bi-motored transports.

The "Whirlwinds" are of the celebrated line of Wright Engines which powered Colonel Lindbergh's memorable flight from New York to Paris, Kingsford-Smith's flight around the world, Adeline Byrd's flights over the North and South Poles, the Key Brothers' world endurance record of 653 hours of unassisted flight and many other famous ocean flights and endurance records.

*Economy of operation, dependable performance and advanced features of design, such as the new Wright Dynamic Engine, which eliminates torsional vibration, are factors which have given Wright aircraft engines world leadership as power equipment for modern, high-speed transports on leading air lines throughout the world.*

## TWA SKYLINERS GET EXTRA SAFETY OF GOODRICH TIRES

### Husky Low Pressure Silver-towns Help Keep TWA Planes 'On Time' - Cushion Landings

WHEN TWA's "Sky Chief" and other famous TWA planes strike across America, they're surrounded with every safety device known in air travel today. Ground-to-air . . . automatic stabilizers . . . lighted airways . . . two-way radio communications . . . there are actually 62 carefully selected TWA men on the ground for every plane shift! And to give these planes real flying safety, TWA chooses dependable Goodrich Low Pressure Shockstruts.

### Flexibility and Strength

In Subertowns, low pressure construction reaches the peak of efficiency. Here is a greater ground contact area, a better footing for soft, treacherous ground. A giant "gullfin" that swallows bumps without jolt or jar. And a tire that locks up this matchless landing ease with plenty of reserve strength in both tread and carcass.

If you want the extra handling safety that leading pilots, phone makers and air lines get with Silverstone—if you want tires that will "sturd up" for hundreds of landings and thousands of miles, choose Silverstone. See your nearest Goodrich dealer without delay, or write Dept. 601, Aeronautical Division of the B. F. Goodrich Company, Akron, Ohio, for complete information about Goodrich Airplane Silverstones and over 40 other Goodrich quality rubber products for airplanes.

**Goodrich *Airplane* Silvertowns**  
THE SAFEST AIRPLANE TIRE EVER BUILT

Over 40 Rubber Products For Analysis - Including Tires - Tire Valves - Air hoses - In-cars - Valves - Rubber Hoses - Cords - Black Absorbent Grease - A Complete Line of Rubber Associated Accessories

**SPEED — COMFORT —  
SCENERY, TOO!**

Besides offering the services in safety and insurance companies, this is known to the airline that shows passengers work progress and capabilities as well as United Express from the air, the Federal Reserve, Meyer Group, American Airlines, Village, Meyer Group and of course, these new services of the air take off our land on Goodrich Aerospace.

WHETHER YOU FLY, SEE HOW MANY TIMES YOU  
TAKE OFF OR ARRIVE WITHOUT DELAYING

## DOUGLAS... THREE

**TIMES DAILY AROUND THE WORLD**

**DOUGLAS LEXFRY LINERS** now fly 75,000 miles . . . more than three times around the world . . . every day. Operated night and day in twenty-one different countries and through all extremes of weather these airplanes have demonstrated their unsurpassed performance. A record of 98.8% schedule efficiency has been set in the first eight months of 1935 on airlines of North and South America. And since their introduction a year ago Douglas Transport

have flown more than twenty million miles.

## Bundles for China!

THE GLENN L. MARTIN COMPANY  
BALTIMORE

Builders of dependable aircraft since 1909

California's coast fades. The new Martin-built China Clipper on her way—carrying Orient-bound bundles. More than 1, persons tried to book passage for her first Pacific crossing. • 1 the China Clipper's sister ships—the Hawaiian Clipper and Philippine Clipper—will join her in Pan-America's round trip to China. • Spanning the Pacific with men, merchandise mail—many times faster than the fastest steamers—these Ma built Clippers are the twentieth century's greatest contributic world commerce.

## AVIATION for December, 1935 \* \* \* \* \*

Edmund T. Allen

The author recently delivered a paper on transport cruising control before the F.L.F., Germany's No. 1 aeronautical body. During his visit he was given unusual opportunity to see something of the rebirth of German aviation. We cannot at a rare privilege to be able to publish for the first time in the United States an eye-witness account of Germany re-erecting herself in the air. This is the first of several articles.

## New Wings for a New Germany

By Edmund T. Allen  
Consulting Aeronautical Engineer

First steps: The building and flying of model airplanes is an indispensable experience for future pilots.

IMAGINE, if you can, our own Air Corps, our entire Naval Air Service, and the Bureau of Air Commerce rolled into one and multiplied many-fold, and you have a picture of Germany's united Air Ministry (Inspector Wirtgen Field, the Naval Air Service, the National Advisory Committee for Aeronautics, and the Bureau of Standards standardized and you have something like the present German D.V.L., *Deutsches Versuchswesen für Luftfahrt*). Insurgent, finally, a sort of super-tribune of the Aeronautical Sciences, with technical subdivisions headed up by the best known aeronautical experts in the country, not only performing its own research and development in every line of aeronautical activity, but coordinating all other agencies, acting as a clearing house for development work, allocating funds for specific research projects to any agency that seems best equipped for it, clustering duplication of effort in all departments, and you have some conception of the enormous *Versuchswesen für Luftfahrtforschung* (General von Seebatz says by Air Minister Hermann Goering), popularly known as the V.L.F.

Back up this vast system of a coordina-

ing bureaucracy with an unbelievable abundance for matters strategical shared by the military and the civil population alike, and you have some idea of what aviation has come to mean in this New Germany. There, things are coming true which might seem to us in America as the dreams of a distant future. Nothing means impossibility to Germany's aviation planners. All differences have been swept aside and all factions have been united. Germany now has an Air Ministry as efficient centralized as Mussolini's own, but made more efficient, perhaps, by Prussian genius for organization and Prussian capacity for taking infinite pains over the smallest detail. We had a public suddenly awakened to the issue of aviation, suddenly determined to build a new and greater nation of flying men and air-borne commerce.

The traveler returning to the United States to report an aviation observed in countries overseas about which great controversies exist, must be prepared to accept all sorts of labels. He will be stamped unscientifically as a communist or as a nihilist, or as a dingo who uses only what he was supposed to see, or else as one whose preconceived notions made

a responsible for him to see anything else but the things that he wanted to see. I still have to risk that sort of thing in describing what I saw in my visit to Germany in October this year.

Although economic recovery may be more apparent than real in Germany, certainly it makes a pronounced impression upon one who is accustomed to see kinds of unemployed shacks in Chicago, abandoned houses in Los Angeles, one has to look long for mansions in Berlin and for standard properties in South Germany. Unemployment is not more than 1,600,000 in the official figures for 1933 as compared with 4,000,000 in 1932, but wages are extremely small. One hears, even among the unemployed, talk of opportunities for sacrifice rather than of rights, especially without salaries. Quite likely the laborer's willingness to work hard for the barest living very fully has helped that everyone is doing it and that the government has ceased equal sacrifices from the wealthy. To me, however, I did not hear any wealthy complaining of their tax burden. Compared with my recollections of the Germany of 1912 and 1913, with its collapsed monetary system, and my acute vivid memories of the despair in the Germany of 1929, Germany in 1935 appears on the surface, at least, to be a land of paradise—out of dreams but of these illusions. Taxes, salaries, and schools are being with society. Audiences are busy with traffic and the sidewalks are carrying capacity loads. As far as the road industry is concerned, anyone with the slightest stretch experience has several jobs open to him, although, of course, the pay is small.

#### The new defense

In order to appreciate the feelings of the extreme interests toward the aviation interests of Hitler's government, it is necessary to understand thoroughly that in Germany the Air Corps is not an adjunct of the army or of the navy, but is in fact the last line of defense. To be an officer in the Air Corps is among the greatest honors for which one may aspire in Germany. It carries more prestige than wealth or the most pos-

Blind flying. From model flying to soaring blind flying is no more odd. Here a group of the standard southern Luft force of 10 personnel from a glider camp during a special display by the German Air Force.

sition. To the air defense of the entire apparatus are made with enthusiasm, conducting strictly with the resistance with which lands are made available to the air arm of our own army and navy. Even the laborer demonstrates his love for the air, as he now sails his wings with the light of faith in his eyes, contributing to the "house" to make Germany first in the air. That is an achievement in need of psychology quite without precedent in modern times. Thus the man in the street points proudly to the new Air Ministry building now rising in the center of Berlin, saying it is a symbol of safety which the Versailles treaty never gave him.

Aeronautical education begins with the very young. The Air Ministry sees it that aviation associations are fostered even in the lowest grades by distributing a weekly periodical devoted solely to aviation to all members. It is intended to help them answer accurately the questions put to them by their parents, and also enables general talks on aviation for elementary use. Departments are assigned to model building, gliding and starting and to the new heroes of the air in sport, in transport and in the Air Corps. The idea is fostered that the modern student is skilled because he has been here in a new world of the air. The is the keynote from kindergarten up. Model-making begins at an early age and progresses

from the construction of the simplest type through a detailed study and reproduction of the products of the German factories and those of foreign types. German students turn out jobs which are marvelous for accuracy of detail and for high finish. In this way they absorb their aeronautical subject-matter at a very early age. An important part of the model program is the design and building of model gliders. Model gliding units are held which reproduce the appearance and the characteristics of the full-scale glider design.

#### The glider camp

To begin of primary school age is opened up the process of spending a summer in one of the many glider schools now established in Germany. The courses are generally similar to those used in this country, with three grades leading up to the finished soaring pilot. The courses of each of the three grade requires four weeks of study and at flying, as well as glider repair, design and construction. A typical aviation training camp is the one at Hohenberg near Stuttgart. In this camp alone 150 students are enrolled each month. Here one is to find modern dormitories, swimming pool, tennis-halls, skating rinks, amusements and bungalows. Here also is a glider factory. In each of the bungalows are stationed that there were 30 sets of places of the latest standard type

In Germany there has been a station in flying requiring 300 hours to complete, about ten hours only in dual. If preliminary soaring instruction made possible a reduction of the dual time by as much as 50 per cent, it would make only a difference of 15 per cent in the total. I asked further whether a pilot who would successfully fly a single set of its absolute ability for a long period of time would not be able to arrive at the 300-hour stage in powered flying in about 100 hours. The reply to that was that while it might be true, most of the glider pilots did not attain such a high degree of proficiency in the training schools. The airplane pilots who make the remarkable short-landing flights, blind-flying into their own camps, are almost without exception advanced students with more than the usual three months' training given in the pre-Air Corps gliding courses.

**Soaring economy**  
The principal contribution of the soaring school experience to pilot training is said to be the economical character of students temporarily released for flying of any kind. Without the preliminary soaring school, it might be possible to train 100 pilot units at \$30 applicants at an average cost of \$10,000 per applicant or \$30,000 per graduate. The soaring school, on the other hand, with extremely low operating cost and low overhead, might easily be expected to reduce and to eliminate these units for flying at a fraction of its figure. Taking a hypothetical 300 applicants as 100 graduates, the final net eight applicants \$12,000 per graduate instead of the original \$30,000.

According to the best figures available, it is quite an inspiring sight to see 50 such perfect specimens lined up with wings sweeping awaiting their turn to enter the wind tunnel. In the way, his almost entirely replaced the former practice of interminable or airplane tow-out. In every place it is considered to be the method of hand launching proved at times where favorable winds prevail. In a later article something will be said of the wind conveyor and the technique. Suffice it here that it is one of the improvements that has helped put German glider pilot training in a new category, both as to time and to expense.

At Hohenberg, as at all other glider camps, the course is under the direction of the military authorities. A commander, a chief flying instructor and many assistant instructors are assigned to the camp. Students are selected from lower to higher pilot grades in accordance that are almost religious in character.

Blind flying is required of all glider pilots completing the highest grade. This and bank induction are installed in all the final stage students. So-called steering is by no means blind flying, a great deal of practice in instrument flying and in blind navigation is thus obtained. I asked one of the gliding instructors at Hohenberg whether or not the glider course decreases the time required for Air Corps flight training in powered

ships. He pointed out that in a course in flying requiring 300 hours to complete, about ten hours only in dual. If preliminary soaring instruction made possible a reduction of the dual time by as much as 50 per cent, it would make only a difference of 15 per cent in the total. I asked further whether a pilot who would successfully fly a single set of its absolute ability for a long period of time would not be able to arrive at the 300-hour stage in powered flying in about 100 hours. The reply to that was that while it might be true, most of the glider pilots did not attain such a high degree of proficiency in the training schools. The airplane pilots who make the remarkable short-landing flights, blind-flying into their own camps, are almost without exception advanced students with more than the usual three months' training given in the pre-Air Corps gliding courses.

**Soaring economy**  
The principal contribution of the soaring school experience to pilot training is said to be the economical character of students temporarily released for flying of any kind. Without the preliminary soaring school, it might be possible to train 100 pilot units at \$30 applicants at an average cost of \$10,000 per applicant or \$30,000 per graduate. The soaring school, on the other hand, with extremely low operating cost and low overhead, might easily be expected to reduce and to eliminate these units for flying at a fraction of its figure. Taking a hypothetical 300 applicants as 100 graduates, the final net eight applicants \$12,000 per graduate instead of the original \$30,000.

According to the best figures available,

able, these units to be a training capacity of between 3,000 and 5,000 glider pilots per year in all the German glider schools. This figure probably does not include those graduating from soaring schools and training power flight training, but rather covers the original number of applicants, some of whom are to be eliminated during training. All those not needed out during the soaring training are given an opportunity after graduation for entering a power flight school.

#### Over 2,500 pilots a year

Soaring training is not, however, a prerequisite for power flying. As many new flying students are taken directly into some flight units as through the soaring grades. The training centers for the Air Corps are trained through Germany. The centers of training are quite similar to ours but at present are being condensed and accelerated owing to the concrete order that pilots must be available immediately to enter the over-organizing force of our army now coming from German borders. As well as pointed out in a later article, an estimate of the production rate of recruits in Germany today runs the figure at between 3,000-4,000 units per year, precisely, all of military type. Pilot training units, of course, lag somewhat behind this figure, but it gives an idea of estimates that the flying schools of Germany are training out trained pilot personnel at the rate of 2,500 to 3,000 men per year. These are the peak of Germany's push. This is the reason for the new German air power.

Mr. Allen will continue his discussion of aviation in Germany in an early issue.

Power flying, the goal of the model-builder and soaring student. A group of Hohenberg school in Hohenberg's Transport for the 1935 training.

*In emergencies, the human mind is most likely to act according to its earliest training. If a pilot has been taught to fly by instruments from the beginning, he will rely on instruments instinctively when the weather closes in.*

## Instrument Training from Scratch

By T. Lee, Jr.

Manager,  
Beech School of Aeronautics

ONLY one glimpse of the ground in his first 24 hours of flight instruction is the unique experience of one Boeing school student. Raymond Schwartz is beyond doubt the first airplane pilot in the world to be trained on instruments flying from the very beginning of his career. His single flying glimpse of the earth below was momentary and appeared when he was on the hood of his training plane, was momentarily covered.

Schwartz, a Boeing scholarship winner, started his flight training "from scratch," under the hood. After six hours of instruction on a Boeing 203 trainer he had made such remarkable progress in flying by instruments alone that we moved on the solo and started giving him instruction on the beam. In fifteen hours and 30 minutes of continuous and beam instruction, he was capable of locating himself and finding the coast of Mexico, in fact, was fully capable of flying the beam. We then transferred him to a Boeing 40, (5,000 ft. 425 hp.) and he made such progress that on his second flight we asked one of the chief pilots of United Air Lines to fly with him. At the lighter ship, he did an excellent job, easily locating the beam, finding the coast of Mexico, and locating himself over Oakland Airport. After 2 hours and 57 minutes of instrument flying in the 40, we decided to put him in the open cockpit, and told him. He solved in three hours

and 55 minutes. Twenty-seven hours after seeing a long line to take to add at first sight, but when that period of dual instruction such accomplishments as complete familiarity with instrument flying methods and an ability to find one's way around on the radio beam, it is exceptionally short.

Schwartz continued his flying until he had 36 hours, much two hours and nine minutes left. We were then anxious to see what he would do if put back under the hood, so we asked Mr. Lott, in charge of the flying of United Air Lines, to fly with him. Schwartz took off under the hood, climbed to 1,600 ft., as safety pilot, reached to 1,600 ft., accomplished a 360-deg. turn to right and left, and saw through radio beam demonstrations of the work before the radio was turned on. He then located the beam, found the coast of Mexico, flew out to the San Francisco beam, turned around and came back on the beam, losing altitude to 1,600 ft., and again located the coast of Mexico. From the coast, he had reduced by compass and time for one minute and fifteen seconds, executed a 180 deg. turn, losing altitude to 300 ft., in the turn, and then made a stall at heading at Oakland Airport. During all this time, Lott had not touched the instruments. Carrying out the approach, he was a few feet short, and possibly would have bailed the plane just as the edge of the field so Mr. Lott spread the throttle a little, closed it, and

Schwartz proceeded to come in and bring the plane down to a landing.

The method used in the instruction of Schwartz and others is likely to revolutionize our teaching at the Boeing School. For a long time we have believed that instrument training should be a form thought rather than an afterthought. We have gathered ample evidence that beginning impressions are more lasting than those experienced subsequently and that, in times of extreme mental stress, one is most likely to act in accord with his early training.

Shortly after beginning the experiment with Ray Schwartz, we started two other students, and two months later, we started six additional students in this type of instruction. The second was, also a W. B. Boeing Scholarship winner, had two years of training at the University of California, in the College of Fine Arts. He did not have a technical background nor did he have any real practical experience or knowledge of instruments, and we were interested to see his position in this type of flight instruction. We find that he has learned to fly by instrument and radio just as well as our first student.

We find difficulty with the average student in getting him to make his concentration to take into account such instructions apparently so well as to interpret the readings in relation to the readings of other instruments. It is our belief that

during twenty hours of instrument flight instruction, we can come nearer to evaluating the mental caliber of a student than we can in several times that number of hours' training on the conventional order of flight instruction. We have found some students who, under the old method of learning to fly, would not and come to a certain stage of training during the 20 or 30 hours, and then not be able to progress beyond that point. In nearly every case it has been lack of imaginative, and mental lag. Instrument and radio flying under the hooded cockpit at first will enable us to discover quickly whether a man has the necessary mental equipment to become a good bad-weather pilot.

In February, 1933, issue of AVIATION, an article "Under the Hood," by Messrs Myers and Karst, of the Boeing School analyzed the interest of the military authorities in England and led to correspondence with the British Air Attache at Washington. This correspondence dealt not only with instrument and radio flying, but also the equipment we planned in ground. With this instruction from scratch. As a consequence the Royal Air Force sent to the Boeing School Group Capt. H. G. Smart, Squadron Leader G. S. Osborn, and Flight Lieutenant G. M. P. Barrett, to make a detailed analysis of the instru-

His first progress could be noted by instrument students, whom first 24 hours more than without knowing the ground.

From England in five previous came three (left) Air Force officers to study instrument flying methods. Left to right: George E. Myers (Boeing School), Squadron Leader G. S. Osborn, Capt. H. G. Smart, P.M. (left) H. M. P. Barrett, Larry B. Long (Boeing School).

ment and beam flight instruction and particularly to see what was being done with instrument radio beam flying under the hooded cockpit for beginning students. These three officers have now completed their investigations and have returned to England with their findings.

In the clear beginning Sept. 30, 1933, we equipped another primary training ship for instrument flying under the hood and started seven more beginning students in this method. We are now so

completely sold that we believe all students taking instruction for long-time courses, such as our Airline Pilot course (250 hours) should begin their flight instruction with instruments under the hood.

Beginning impressions are usually the lasting impressions. By starting a man in "blind" we try to condition him so that in times of stress his reactions will be sound. Such a man should make the best kind of bad-weather pilot.

Fig. 1. Progressive strength of flat sheets of aluminum alloy 7575-T6.

AS WAS SHOWN by Bureau of Standards tests, the load carried by flat sheets having uniform edge supports varies with the sheet thickness but is essentially constant for all widths and lengths so long as the sheets are flat. The tests showed that the maximum load for sheets could be predicted quite closely by the use of a formula of the type

$$P = A t^2$$

where  $P$  was the maximum load,  $A$  a constant and  $t$  the thickness of the sheet. Korman, Seckler and Donald in their paper "The Strength of Thin Plates in Compression" (Transactions of the Applied Mechanics Series, A.S.M.E. January 1932) presented a generalized formula

$$P = C P_y / E t^3$$

where  $P$  is again the maximum load which the sheet will sustain;  $C$  is a constant;  $t$  the sheet thickness,  $E$  the modulus of elasticity of the material,  $P_y$  the yield point strength. For aluminum alloy sheets (7575-T6) it has been found that  $C = 3.75$ ,  $E = 16,000,000$  and  $P_y = 36,000$  are good values to use in this formula when the simplifies to

$$P = 1,960,000 t^3$$

Fig. 1 is a plot of this expression and the points marked "B" represent the values obtained by the Bureau of Standards tests.

Figures 2 and 3 are purely empirical and give the two factors,  $K_1$  and  $K_2$ , by which the maximum load on a flat sheet may be multiplied to give the maximum on a curved sheet. They were developed from the test data obtained at the Massachusetts Institute of Technology on curved sheets of alumi-

nium alloy of various widths, lengths and thicknesses. All were supported between two supports and all were processed in the radius desired before being put into the testing machine. Widths of 3, 6, 9, and 12 in., lengths of 6, 12, and 18 in. and thicknesses of 0.035, 0.052 and 0.082 in. were tested

in radii of 5, 10, 20, 30 and some of 40 in., as part of the program to obtain data on curved sheets in compression. It has been found by checking against other available test results that the length factor,  $K_2$ , can be plotted for radii up to 24 in. and still give satisfactory results. It has also been

stated by adding  $n$  times the maximum load provided for each stiffener to  $n+1$  times the load for each sheet,  $n$  being the number of stiffeners added. The results of this analysis are shown in Figure 10. The difference between the loads predicted in this way and those from test is quite satisfactory for the thin sheets with a type A stiffener and for the Buckle sheets with stiffeners spaced at 0.050 in. Sheets with stiffeners spaced at 0.050 in. showed a difference with the type A stiffener because the light stiffener is not sufficient to make the sheet remain smooth in the vicinity of the stiffener so that it is not possible to make a smooth curve. A definite difference has yet been developed for the stiffeners which is necessary to break a panel up into 4 sheets but it can be said that it is in the final corner of the panel. The results of the analysis of stiffeners are shown in Figure 11.

Fig. 5 presents what might be considered the most important results of the present study. It is seen that the maximum stress in the stiffener is not at the ends of the stiffener, but is at the center. This is in contrast to the results of the previous studies, which showed that the maximum stress in the stiffener was at the ends. This is due to the fact that the stiffener is now considered to be a beam, and not a plate. The stiffener is now considered to be a beam, and not a plate. The stiffener is now considered to be a beam, and not a plate.

## Nose Wheels

By  
Capt. Frank T.  
Courtney

**T**HIS time when, as an essential part of a leader's growth is not new. Many a mid-timer, like the wiseacre Curtin, probably had a few wheels well behind the C.U., well the more wheels taking its last breath of growing load. The arrangement, however, was abandoned long time ago. It is rather now an era of the higher loads and leading speeds without benefit of the steady accumulation of experience which has gone into many great and tall wheel designs in the last twenty years.

This wrecks disk primarily with the type of gear in which the mass wheels are behind the centre of gravity, and the mass wheel is a disk. Certain types of ground-spreaders, for example, have a disk at some point with which the disk does not usually rest on the ground wheel but was fitted with one for one reason or another, usually to permit the mass wheels to be put in front to the C. G., or just because it was a disk. The disk was not intended to be a mass wheel, and it caused these troubles which they were designed to eliminate. It tended to emergency or emergency division only, they were made of metal or woodwork construction, and they were not made of metal on them. The material was not the broken parts almost invariably dug into the ground, and

which might have been a terrific nose wheel because a highly efficient trucking [A number of examples of nose wheel applications of this type are shown on the page opposite. They belong to the period dating and immediately following the First World War, and are undoubtedly a hangover from the days when a long nose told you (usually) moment before the wheels, propellers will forward. The war's Funnies and Caudrons exhibited few failures. It persisted into the early 1930's on the British Avroa. Going back further into history, the control side was concerned the main landing gear member, the wheels being originally as well as today only—[6]. I have seen old F.I.E. pictures test over with and without the nose wheel. Without the wheel the front of the machine was pulled in with slight damage. But with the broken wheel parts digging into the ground, the landing gear usually suffered partial collapse, and the ship slid over one side of the triangle of support, smashing the lower wing and throwing the machine over sideways. On early Marmonde floats an attempt was made to avoid the triangle effect by putting two small wheels out in front. I have reason to remember this arrangement well. Once when I was a navigator, it seemed a simple task to crash in just after he had bailed out one. His ship, running over rough ground, loaded back and forth from nose wheels to tail wheel until (instead of merely bouncing as might have happened with a conventional) both front wheels broke off. The broken parts dug in and turned the ship on its back in a horrendous expense some read.

Nose wheels, therefore, should not be considered at all unless they are designed to take the full loads that may be put on them. How much these loads may be we shall see presently.

#### Why a nose wheel?

First of all, why use a nose wheel landing gear at all? The strongest reason is to permit the full application

Fig. 1. Importance of placing nose wheel well forward on aircraft.

The nose wheel must be a standard feature of every fighter machine.

of brakes for shortening the landing-run, an obviously valuable feature. (This can be accomplished with the usual gear by putting the nose wheels far forward, but this involves a strong tendency toward ground-looping and certain take-off difficulties.) A less obvious advantage, but a very important one, is the clear view ahead of the aircraft (due to the level position of the ship) when taking off and during the run after landing. The likelihood of the conventional surprise under these conditions—particularly at night or on bad ground—is certainly only because we have had to get used to it. [See also "Guns" by Ralph H. Upson, *Aviation*, October, 1935.]

Sometimes structural consideration in the airplane makes the selection of a gear wheel gear necessary. In the recent Curtiss-Wright amphibian, for example, the main wheels could then be placed far enough apart to attract them into the hull instead of into the cabin, where space was at a premium. Again, when a ship on three wheels is at rest on the ground the wings are at a small angle of attack, greatly reducing the risk of blowing over in a strong wind. The slight advantage of being able to land at any angle doesn't suggest one. Almost any ship can do this if it has the shock absorber capacity.

#### Design and construction

Certainly a large number of factors affect the nose wheel which accounts for the design of a tail wheel. The width of the main gear, the power of the brakes, the height of the thrust line, the force of the thrust, the height of the C.G., the diameter of the wheel for gear power other than land, the steering factor, and (there is also much for the system built) the structure.

Consider now the nose wheel gear must be constructed and installed. The first point of importance is the position of the main wheels. If they are too far

back, the loads on the nose wheel will be unnecessarily increased and, on the reverse, the same may result down too long. A good rough guide is to place the main wheels so that in the most unfavorable condition they are very slightly behind the C.G. at rest. This gives the pilot the most effective control over the attitude of the ship under such conditions. The nose wheel should then be placed as far forward as possible. In fact, if it is not possible to put the nose wheel well ahead of the C.G. it should not be used at all. If the front wheel is too close-coupled, but backing in likely to be experienced when running on the ground. Also, since the nose and main wheels form a stronger support for the ship, the nose wheel will prevent a three-dimensional nose-over but, at the same time, a sudden increase in the ship can turn over about one of the forward sides of the triangle. Figure 1 shows the importance of the far forward wheel under such conditions. Again, the farther forward the wheel, the less will be the load on it when the nose is dropped on the brakes applied.

So much for the position of the wheel. Consider now the construction of the nose wheel gear. The worst condition for load is the application of brakes when the ship is still moving fast with the nose wheel well off the ground. (This condition is actually worse, but unless it can be dealt with, much of the advantage of the nose wheel is lost. My own technique for braking at high speed is to drop or push the nose wheel onto the ground first and then immediately apply brakes, but I doubt if this procedure can be counted on.) This puts a heavy vertical load on the nose wheel, which is usually a tail wheel would be called upon to stand. The higher the C.G. the greater this load will be. This means that relatively long also travel must be provided, particularly since a very strong spring would cause the ship to back back into

#### AVIATION December, 1935

lightly on the tail. If the nose wheel gear will meet this condition, it will probably meet the "Spring into the ground" type of landing to much restraint, provided this does not involve landing on the nose wheel alone. The long also travel involves a considerable hanging-down of the nose wheel when the load is off, an undesirable feature, particularly where connection is involved. And it means a much heavier gear than a tail wheel gear for a corresponding airframe.

#### Wheel diameter and "skinning"

Regardless of load considerations, the nose wheel must be of relatively large diameter. At take-off, the propeller thrust forces the nose wheel down. As speed is gathered, a down load on the elevator will reduce that load, but the extension of the oleo will leave the nose wheel still running on the ground. The diameter of the wheel selected will therefore be governed by considerations of ground bumps, particularly on muddy ground.

Thus there is the question of "skinning." Without going into the causes of the somewhat common and always objectionable phenomenon, it can be said that it is liable to occur in very normal operating system. But it is likely to be much worse for the nose

wheels all add to the load on a nose wheel. The same factors tend to reduce loads on a tail wheel. The higher the thrust-line and C.G., of course, the greater the effort will be. The landing springs for the nose wheel, therefore, must be stronger and heavier.

Apart from an operating standpoint, structural requirements practically dictate that the nose wheel shall be overbuilt and not loaded. It is easy to see that the large loads imposed on this wheel may have big lateral components if the wheel is bent. If it is found necessary to provide a temporary lock (as in

the case of some tail wheels), the whole affair will have to be made very strong, and relatively heavy. It must always be remembered that failure of a nose wheel, either in take-off or landing, leads to greater damage than a corresponding tail wheel failure. Human probably has one of the greatest objections to the nose wheel.

#### Braking

As mentioned above, the strongest reason for using a nose wheel is to permit full use of the brakes on landing, but that has problems apart from struc-

Which nose wheels were loaded in emergency, as mentioned above, their maximum load was made more than they should be. They should have been loaded, however, on the ground of War and post-War types of aircraft. Above: The British P.E. 1 (right) (British) (1935). Left: An early experimental American tail wheel (British) loaded by the machine in 1913. Below: The British D.C. 3 (1935) (1935) and a pair of wheels under the nose.

which than with a tail wheel because for a given weight of ship, the nose wheel will be larger than a tail wheel, and the forces generated by the shimmy will be greater. If the nose wheel is left free to pivot, it is liable to shimmy violently, if it is locked it will cause troubles as outlined above; and if a sufficiently effective friction clutch is introduced in opposite direction, the wheel may dig in center property, causing excessive air drag or involving restriction troubles.

While taking the thrust of the ship, the application of brakes, or the reaction of ground bumps on the main

ward strength. The fact that the three wheels form a triangle is important. It is the possibility of capturing over one of the forward sides of the triangle under different conditions which is the main problem. Assume the nose wheel locked in landing. It will be seen that if a sudden application of both brakes is accompanied by any side motion of the ship, the ship's momentum will tend to carry it over toward one of the forward sides of the triangle; the ship will not nose directly over, but it will go over forward-and sideways. Now assume the nose wheel to be revolving. The ship has landed with a 90-deg. cross-wind from the right, and the brakes are not at first applied. The wind takes the lip and attempts to weather the ship to the right, the nose wheel offers no resistance to swaying, the C. G. tries to keep going ahead, the right wheel tends to leave the ground, and the ship tends to capsize around the left forward side of the wheel-triangle. But suppose the links are applied (and, cover the triangle of the nose wheel, it is possible to apply them as land on one wheel). Now, if the right wheel tries to leave the ground, the left wheel supplies all the ground-load, the ship swings back toward the left with an resistance from the nose wheel, the left-forward side of the triangle runs away from the C. G. and the ship cannot be captured! At worst it will roll aside, what from side to side, but the ship will not go over completely over.

**Ground looping.** Neglecting air or wind effects, the basic cause of ground-looping may best be analyzed by an example. Consider one a rectangle, one with the axle wheels in the forward corner ahead of the

C. G. (Fig. 2a) and the other with the main wheels behind the C. G. (Fig. 2b). The ship has landed in direction A and not slowing up. Something is out, a storm, disturbance in wheel friction or whatever—starts the right wheel and starts the ship swinging to right. The momentum—applied at the C. G.—tends to carry the ship in direction Z. The momentum makes it roll into two forms, one, Y, tends to

Fig. 2. Forward spring landing gear; (a) rear wheel gear; (b) rear wheel gear.

carry the ship on nosewheel; the other, X, is counter to the body of the ship. Clearly, in the case of Fig. 2a, force X will swing the ship still further to the right, until the wheels, trying to slide sideways over the ground, form an excessive brake and the ship nose over. In the case of Fig. 2b, force X tends to pull the ship toward the left. Thus the C. G. behind the main wheels encourages, and the C. G. ahead of the wheels discourages, ground-looping tendencies.

This is, however, not of much help in a cross-wind landing because as that case the wind will catch the lip and, in fact, the nose will swing, producing the dangerous tendency referred to in a preceding paragraph.

If, to meet this situation, the nose wheel is to be locked, then the nose wheel has no great advantage over the tail wheel. If, instead, the nose wheel is to be locked, it has to be designed so that it will not lock on the ground if the ship swings, and then opposes ground-looping. The nose wheel has the slight advantage that, if the brakes are applied hard, the locked nose wheel will tend to remain pressed hard onto the ground, whereas the locked tail wheel will lose its pressure on the ground and possibly slide sideways.

Taking all factors into consideration, I have reluctantly come to the conclusion that the possibility of ground-looping is not much of an argument in favor of the nose wheel. The locked tail wheel does much more for a good job for much less weight.

Practically the same points apply to the movable nose wheel as compared with the body swinging or locked wheel. A steerable and wheel will do about as well, but, being necessarily smaller and lighter, it will be easier to control.

#### Take-off

The nose wheel arrangement is, probably to a considerable extent, detrimental to take-off characteristics. The thrust of the propeller tends to press the nose wheel down on the ground at a rate where a tail wheel would be lifted off the ground. The higher the thrust-line, the greater the down load. Thus there is the added friction of the nose wheel during the take-off run, and the added resistance to air ground. The pilot tends to relieve this load by pulling back on the stick during the run. This, however, usually adds to the weight of the ship applied at the nose wheel by the down load on the elevators whereas, with the tail wheel, the elevators are used to reduce air drag. As a factor, incidentally, which is often forgotten in considering the take-off of airplanes.

These various points in consideration might be elaborated upon almost indefinitely, but I think much has been said to show that the nose wheel gear is not simply a matter of getting a wheel out in front. It is a considerable matter involving many other factors in the design of the ship and in its operation. I personally feel that the advantages of the nose wheel landing gear are such that further study and development should be encouraged. But I certainly do not feel that its advantages are so pronounced and obvious as to lead it to be specified as a premise for all very landing troubles. The real solution of the problem is, of course, two overriding nose wheels widely spaced, but weight and other considerations readily show that one of present politics

AVIATION

AVIATION  
December, 1933

Except for the Affair of the Canceled Contracts, few questions have agitated the aviation industry as violently of late as has the Vidal airplane-in-every-garage idea. To find out just what the industry thought about it, Aviation circulated a questionnaire. Here are the results.

## This Light Plane Business

AVIATION'S survey on the Vidal airplane program. Distribution of questionnaires and replies.

Class	Number	Positive	Not Quite
Aviation Manufacturers	101	10	41.3
Engine Manufacturers	26	11	42.3
Airplane Manufacturers	10	10	100
Flight Test Divisions	100	10	10.0
Private Owners and Pilots	243	10	4.1
Aviation Officials	112	10	8.9
Manufacturers	24	10	41.7
Total	1,117	509	45.5

IN SPITE of showers of dead cats and broken bats, a great deal more sympathy here to give the Bureau of Air Commerce powers to develop its airplane and its airplane for the private market than now popularly supposed to exist. Taking the overall result of AVIATION'S survey of industry opinion there is almost a two to one vote in favor of direct government by the Bureau. But to carry this figure without qualification would be decidedly misleading because, as shown by the table below, in important industry groups, the rate does not hold. In fact, aircraft manufacturers show a complete reversal, being pretty two to one for the opposition. As might have been predicted, the producing groups took with little favor on any effort of a governmental agency to undertake development work in their particular industry, or to exert undue influence upon established trends or design thought. The consumer groups, on the other hand, (the final base operator, the private owner and the private pilot who is a prospective owner) welcome for the most part

what the change in that case was that the wording of the question was "favor to Vidal?" One of the most interesting and important features of the survey is in the comments which accompanied the replies. A great many people took advantage of the invitation to supplement their votes by some extensive comments. In following over the comments one better had to be kept definitely in mind and properly directed. People who were in favor of any particular item on the questionnaire were generally less cautious than those who were opposed to it. Thus, in evaluating the group opinion on any question, it was necessary to qualify the general trend of the comments by giving due consideration to the statistical count of the votes. It is to be expected that some limitations forbade the quoting of more of the comments in full. Many were interesting. Almost all were constructive. Altogether they would fill many pages of AVIATION.

Among those who favor the Department's program as a whole was a feeling that the aircraft industry lacked the necessary broad give vision to see up private owner requirements. One found here specific need: "Someone should do the job. Why not the Department of Commerce?" Others felt that the industry not only lacked the vision, but the necessary funds to carry out a broad development program and therefore with a project should be sponsored by the government. It was

A recent example where the nose wheel is an essential part of the landing gear, with the airplane C. G. ahead of the main wheels—the Vidal experimental light airplane. The nose arrangement has been used on both the De Havilland and Westland ships, both to meet the requirement of a crosswind light plane operation.

Altogether 396 specifications for the ideal type of aircraft.

**QUESTION 8.** Do you think that the Department is on the right track in trying to convert automobile engines to jet power? Yes/No?

Class	Yes	No
(per cent)	(per cent)	(per cent)
Airline Manufacturers	19	81
Engine Manufacturers	36	64
Aircraft Manufacturers	22	78
Fixed Base Operators	33	67
Private Owners and Pilots	36	64
State Aeronautics Offices	22	78
Manufacturers	30	70

**QUESTION 9.** Assuming that engine could be easily converted to jet, and light weight, could we afford to put jet power plants in place of the now weight and the same power as the old? Yes/No?

Class	Yes	No
(per cent)	(per cent)	(per cent)
Airline Manufacturers	24	76
Engine Manufacturers	12	88
Aircraft Manufacturers	10	90
Fixed Base Operators	15	85
Private Owners and Pilots	17	83
State Aeronautics Offices	14	86
Manufacturers	18	82

for the private market were analyzed and tabulated. These yielded a general level of opinion of the various groups toward questions of capacity, landing speed, top speed and range.

Looking at the capacity table, it is apparent that the trend of opinion was toward the less airframe-type jet in growth only of groups. Airframe manufacturers followed this general trend but the engine and accessory people generally wanted larger airplanes, referring to the four-place type. The fixed base operators' opinion reflects not only their own desires as pilots and operators but also something of the requirements of their potential customers as distributors. The private owner and private pilot note follows the fixed base trend very definitely. Obviously few people as yet are thinking of the airplane in terms of a family car.

The vote on landing speed covers a range from the widely differing of the pilots and private owners, through the more practical limitations of the fixed base people, to the opposing analyses of the manufacturer. Thus the latter's analysis of opinion of the private owners and pilots falls on a landing speed of about 30 m.p.h., the fixed base operators on about 40 m.p.h., and the manufacturers closer to 45.

For top speed, no group came into a life or death argument in terms of contrast talk of speed and more speed, it is

apparent that engine conversion would be consistent with an airplane which showed a top speed in the neighborhood of 125 m.p.h. Quite a few fixed base operators and pilots would be willing to drop well below this limit and would get along with speeds ranging around 100 m.p.h. This trend is, of course, tied in with the desire to use engines of reasonable horsepower operating at reasonable cost. Again, as might be expected, the engine manufacturers who voted backed toward much higher speeds and therefore to much higher power requirements. Range requirements are also reasonably modest. The 500-mile figure seems most frequently, possibly because it is a good round number, but more likely because it is well within practical limits and gives the prospective user a chance to really go places with his airplane.

Somewhat up, the general consensus of opinion seems to be for a two- or three-place airplane, landing at 40 m.p.h., with a top speed of about 115 and a range of 500 miles. One fixed base operator said, "The average pilot can handle a plane easily for pleasure. Give him a conventional looking airplane, sized, and not too noisy, slow but not too slow, one that will hold on a golf course."

#### That engine question

The part of the Department program concerning the adaptation of automobile engines to aircraft has been subject to the most violent discussion. Again, as with the general vote on the whole program, the two groups engine, producer and consumer. The three manufacturers' groups must, however, stand alone against any attempt to modify automobile engines for aircraft, but the owners and fixed base operators as a group are pretty much on the fence with an almost 50-50 vote. One thought the idea was "too radical," another favored it "if this work will get some large manufacturer into developing an engine designed for airplanes," and another voted "yes" because "We are going to have to sometime operating at lower rates and that certainly can't be done with present power plants."

The question covering engine weight was perhaps a bit too sensitive. Many who liked automobile conversion in Question 9 were apologetic about it at the cost of much extra weight. The general consensus was definitely against any weight increase although there were a number of people who felt that improvements in general aerodynamic efficiencies could go a long way toward offsetting the extra penalties. One fixed base operator considered it all right for short range private ownership or fixed base training where reliability and economy are more necessary than weight economy. "Owners and operators are not as weight-conscious as the engine manufacturers who say that 'engine weight involving starter, generator, fuel pump, propeller belt, petrol cooling and exhaust system, must not be over 2 lb. in the horsepower, and perhaps less.'"

It became obvious from the trend of replies to Question 10 that the horsepower grouping was badly confused, particularly in the 100 and 200 hp. class. This range should have been broken down at least into two groups, one of which ran from 100 to 125 and the other from 125 to 200. Scanning up the tables and the general level of comment however, it is apparent that the majority opinion favors an engine of about 100 to 120 hp, although the fixed base operator group seems with an eye on economy, to willing to drop under that figure, centering probably about 80 hp. A good many for sentimental reasons, perhaps, held up "the good old GX-3" as a mark in aim at for the conversion.

## Editorials AVIATION

### Watch Those Wires!

TO ONE who has any occasion to see the airlines or to fly cross-country can be out of sympathy with a movement now afoot to eliminate all overhead electrical wiring from the vicinity of landing fields. We are hooked 100 per cent. All too often we have felt decidedly uncomfortable dangling into certain fields over a network of "hot" wires. It is bad enough in the daylight and clear weather. But at night, especially in fog, those wires actually seem to be reaching out to trip us up, until the wheels crash down on the runways.

Here is a type of hazard to which aircraft should not be exposed, and one that can be eliminated of sufficient pressure is brought to bear. There can be no better place to apply funds now being made available for airport improvement through WPA and other agencies than in getting power lines away from the edges of flying fields, either by removing them, or by putting them underground. Work has already been started in some locations. Groups, notoriously disorganized in their transmission from near the municipal airport, but taken steps to remove them. Other cities should follow suit—and act, before serious trouble occurs. If the owners of power lines are not willing to cooperate voluntarily, money must be found to compel them to do so. Since public safety is involved, the proper city, state or federal authority could and should be invoked to eliminate all such hazards.

### Pilots are People

CONGRATULATIONS to a pair of our popular contemporaries, *Saturday Evening Post* and *Esquire*, for their recent sound and sober articles on air transport. We are making progress indeed when editors of non-aeronautical publications are willing to put into the hands of their readers such sensible and straightforward accounts of how airlines really operate, and what sort of people fly the ships.

If any widespread automation needed de-bunking badly, it was that hanger from the late lamented 1920's that pictured all pilots as dashing heroes, with

"close, grey eyes, blond curly hair, bronzed cheeks" and a thirst for cocklesauce,—gritting the teeth through in spite of hail and high water, barely missing the trees—in the process, milling about in blinding storms with engines straining over the last few drops of gasoline.

All of which made well in the story books, but doesn't help much in looking up trouble for the air lines.

Now the halo is coming off, and it is a good thing. Simply telling people, however, that airline pilots are carefully selected, highly trained and are constantly supervised may be impressive, but is not always convincing enough to induce them to patronize the airways personally. But, there is definite psychological value in getting across to the public that pilots, besides being highly trained professional men, are just ordinary people like themselves, that they have homes and families to get back to when the day's work is done. The presence of the air line pilot returning to his home in the suburbs, picking up a snack from the family freezer, and going out with his wife for a quiet evening of bridge at a table of a next a point with his book clerk neighbor, has in it elements that engender confidence. Such things go a long way toward breaking down a feeling that still prevails that flying, or riding in an airliner is an unusual and risky procedure.

### Safety Measure

A LOT of people were off half-cocked over the order that went out from the Bureau of Air Commerce early in November restricting the use of the airway radio facilities under conditions of limited visibility. If there was any doubt about the temporary character of the original order, it was quickly cleared up at the conference held in Washington last week which is published and on the modification that resulted. A great deal of work still remains to be done before a completely satisfactory solution is found to the ever recurring problem of the control of air traffic for maximum safety, but as a temporary measure, we think that the Department order with its modification of Nov. 15 is fair and reasonable. The government airway facilities are still open to anyone who has two-way radio equipment and can demonstrate his ability to use it. He can't go off and fly for the fun of it near federal airports or terminal airports in bad weather, but if he can go places, all the Department asks is that he fly according to a prearranged flight plan, be subject to dispatcher control at take-off and at destination, and that he keep all concerned informed as to his whereabouts at all times. Surely this is not an unreasonable restriction, and it may be the means of avoiding a major tragedy until some better solution to the problem turns up.

**QUESTION 10.** In your opinion what horsepower engine will be most useful for the most private owner airplane? 10-40, 41-60, 61-75, 76-100, 101-160, 161-200, 201-300, and up

Class	Number	Horsepower (per cent)

# Flying Equipment

THE IMPROVEMENTS in flying qualities and ground handling of direct control autogiros have been discussed frequently but the methods used to solve the innumerable mechanical problems are much less familiar. Through the cooperation of R. H. Proctor, chief engineer of the Kellitt Corporation, we are able to present the mechanical details of the K.D.-1 machine, which have resulted from several years of development and flight testing. The first of these devices is the rotor blade clasp.

This clasp has been devised to limit the oscillation of the individual rotor blades about their vertical hinges. It consists essentially of an (a) spring-loaded, oil-damped, self-centering device. The plunger is actuated by a rotor and double end cam. The entire mechanism is housed within the fork end of the blade spar. (See sketch A.)

On the upper end of the rotor hub (see Sketch B), which is a heat-treated alloy steel axle, are the drop and centering rings and the horizontal attending pivot. On the lower end is the spiral bevel ring gear for the rotor starter. Radial and thrust ball bearings are used in mounting the axle. The lower radial bearing is mounted in the lower section of the two-piece magnesium alloy cast

## AVIATION November, 1933

hub case. Rotor starter pinion and bearings are also carried in the lower section of the case. To the top of the case is bolted the hub cap, a heat-treated machine steel forging, integral with which is the extension for lateral tilting of the hub. From this transverse the flying leads are transmitted to the main armature structure through a heat-treated steel yoke. The hub cap also carries the principal rotor flying leads and only the starting torque and radial loads from the lower axle bearing are transmitted to the magnesium case.

Longitudinal control of the rotor is accomplished by turning movement of the rotor in the forked upper end of the yoke (C). The yoke is attached to the upper fuselage train by bolting to a welded tubular support. At this point all torsion and bending are transmitted from the yoke into the fuselage structure. Axial loads and such side loads as a crash from the upper part of fuselage are transmitted to the

A. Blades are made self-centering by this internal oscillation feature.

D. Starter drives the rotor at a much greater than the necessary for takeoff. Maintenance has been simplified by its design.

lower fuselage train through a forged steel strap fitting at the lower end of the yoke. The entire yoke structure together with the lower hub cap, including ball joints, control rods and cables, are enclosed in a streamlined dual housing. (See general arrangement, p. 30.)

The rotor starter system (D) has been improved mechanically and the most of the maintenance difficulty with earlier forms have been eliminated. A constant torque clutch and the lower gear case are supported by fittings bolted to the lower end of the yoke itself. The clutch is designed to preclude the possibility of overlock being transmitted to any part of the starting mechanism or to the structure itself. As an additional precaution, a ground kick-out lever is connected to the upper end of the upper drive shaft to the auxiliary loop, serving as a safety connection of predetermined breaking strength. Clutch and brake are operated from conventionally mounted control levers in the pilot's cockpit.

To make any improvements in take-off characteristics that may be derived from semi-swinging of the rotor, the mechanism is designed to transmit a load considerably in excess of that

necessary to obtain sufficient rotor speed for normal take-off.

Flight control is accomplished by tilting the rotor about its longitudinal and lateral axes. The movement about the longitudinal axis provides normal, directional control but, for rapid maneuvering, it is supplemented by a steel push-operated rudder. Positive stops are provided for both lateral and longitudinal controls. A spring-loaded plunger built into the upper end of the pilot's control stick furnishes an effective lock. When the stick is pushed hard forward and the plunger is in its extended position, it is guided by two sliding flanges into a cross behind and beneath the instrument board. The control stick and the rotor head is then locked in a forward position and the rotor is maintained in a normal, steady-state while the ship is at rest. This affords protection against high winds and permits take-off in a strong wind without first "tailgating." The stick

lock is usually releasable before take-off. Dual controls are part of the equipment and the system admits needles and self-aligning ball bearings at all external points for angular movement. Control sticks are biased together at lower elevations by push-pull cables for free and all control and transmission to the rotor and head rotor is entirely by push-pull rods and bell cranks; the vertical centering rods being carried independently about the pivot strut. Lateral control is accomplished by a stick operated torque tube having two radial arms to which are connected the necessary cables. These cables operate the lateral bell crank and push-pull rod at the rotor head.

Spring-loaded longitudinal and lateral bearings compensate for side force variations due to changes in flying speeds and the quantity and distribution of load. Both bearings are loaded by the same spring and are connected to the rotor head by means of cables.

The lower shock units are mounted on brackets riveted to the lower diaphragm of the rotor. They connect with maining wires on brackets welded to aluminum support tubes. The latter are supported at their ends and by two brackets from the firewall. They are normally prevented from rotating in their bearings by spring loaded stops. By inducing the stops the tubes may be rotated by means of handles projecting below the board thus relieving the shocks of undue strain on the parts are locked forward. The handles and stops serve to center the panels when folding them back into place.

The upper edge of the three boards are fastened by large angled plate brass thrust sockets which pivot the board and make with a nut riveted to a small flanged dural bar. This bar is attached through shock cords to brackets which extend down from the deck above the board under the windshield. When closed up tight, the thrust sockets pivot the dural bars against the back of the board against a hard rubber block which acts to prevent the screws backing off.

Ordinary left window channel riveted to the flanges at the edge of the panels keep them from jamming against each other and seal the gap between. When folded down, the panels are held in a convenient working position by rubber bands. Either of the side panels may be fully folded down in flight. With help from the cockpit, the outer panel may be opened up far enough (before letting the control column) to permit access to the other and seal the gap between. When folded down, the panels are held in a convenient working position by rubber bands. Either of the side panels may be fully folded down in flight. With help from the cockpit, the outer panel may be opened up far enough (before letting the control column) to permit access to the other and seal the gap between. When folded down, the panels are held in a convenient working position by rubber bands. Either of the side panels may be fully folded down in flight. With help from the cockpit, the outer panel may be opened up far enough (before letting the control column) to permit access to the other and seal the gap between.

There are 109 connections which lead directly to the board through flexible 1/2 inch or wires from a polyalloy of dural mounted on the rear side of the firewall. All bases (plated or riveted) are mounted on the right side of the instrument, are quickly reached by swinging down the right hand panel of the main board. The vacuum regulator for the various drive instruments is mounted on the back of the center panel with its control screw projecting through it. It is adjacent to the

Profile of the 1935 Beech transport.

station gauge and may be regulated in flight. The arrangement makes very low vacuum lead to the board necessary. Heavy rubber vacuum gas tube has been found the most suitable for the purpose.

An interesting feature in the enclosing of certain groups of instruments with a single pattern of yellow bars (4 in wide) is an aid to the pilot's eyes. Thus the avionic instruments are isolated from the others by an enclosing yellow bar. A line also separates the instruments from the light switches, vacuum regulator, thermocouple sensor, rheostat, ammeter, etc., which lie in a line along the bottom of the board. A short vertical bar on each side isolates usually the radio receiver on the left and the transmitter on the right.

Any sort of lighting may be used satisfactorily with this type of board, but it is particularly adapted to a system mounted completely behind the board. Bulbs may be changed easily in flight. The knobbed mounting also affords illumination for any necessary adjustment to the instruments.

## Navy Notes

**A seaplane conversion and the first from the Naval Aircraft Factory**

In August for September, 1935, we described the landplane version of the latest Curtiss-Wright two-place seaplane observation type for the Navy, the SOCC-1. Now comes a picture of the same machine mounted on a single float for catapulting from battle ships and cruisers for fleet reconnaissance work. Altogether 158 of this type (convertible land or sea) are being built for the Navy at the Buffalo plant. Demand for features in the construction of float and floats on the upper wing. Plans call for a Pratt & Whitney engine, a full MAGA cowd with landing gear flap for controlled landing.

Under the recent Vickers bill, 10 per

central training and observation schools is known of its specifications or performance. It appears to be a two-place open cockpit biplane of conventional structure, with landing of welded steel tubes, fabric covered for the most part. The float is all metal but other sections appear to be fabric covered. Power plant is a Wright J-5.

## Beech Transport

**Preliminary reports indicate a two-engine Beech transport in the offing**

Reports have been filtering out at Wichita that a two-engine Beechcraft transport is due to appear some time early in 1936. It is a fact that the machine is being prepared to meet the specifications of the Department of Commerce for a transport for longer line service.

Provision is being made for two pilots

## Instrument Accessibility

**An interesting solution for a tough problem worked out by Viking for Dr. Light's Bellanca.**

SEVERAL months ago (NAVIGATION, September 1935) we described the Wisconsin Bellanca gyrochar built for the use of Dr. Richard U. Light of New Haven, Conn. Now, thanks to Franklin T. Kent of the Viking Flying Boat Company, we have a very complete description of the instrument board installation of that ship, with particular reference to accessibility, not only on the ground, but in flight. The arrangement is concerned by Dr. Light, was carried out by Earl Neill and Franklin Kent of the Viking company.

The board includes seventeen instruments, a number of lighting switches, rheostats, vacuum regulator, thermocouple, and radio receiver and associated controls and covers. With this

large amount of equipment in the space of a normal sized board, accessibility to the back would have been extremely difficult. It was assumed, however, by dividing the board into three panels each of which is hinged about its lower edge, that back would have been extremely difficult.

Each of the panels is counterweighted in a dural sheet hinged over at the edges. To allow the three panels to move independently, a total of fifteen pairs of L-shaped shock absorbers are used, giving freedom of movement in all axes. The axes of the upper shocks are horizontal. The lower are mounted with axes vertical directly under the center of gravity of the assembled board. No vibration or oscillations can be detected on rough field take-offs.

Left to right: General view of board showing yellow line to eliminate inside surface according to location. Note grouping of the rheostat and vacuum regulator in front with light; pressure and Bellanca described the back of the engine and associated instruments except the gyro and battery by Neill and the U. S. Electric Bellanca. Study component includes four main sections and receiver, Washington instrument.

The Curtiss SOCC-1 as a seaplane for fleet reconnaissance work. It is shown here catapulting. The upper wing carries both floats and float.

First product of the Naval Aircraft Factory under Vickers bill manufacturing. The Navy's SOCC-1.

forward and for a passenger cabin with seats for six. Alternate arrangements for three or four people on the executive side will probably be offered. Luggage and ticket compartments will be in the rear.

With two 205 hp engines, the cruising speed is calculated at about 185 m.p.h. The ceiling with single engine is estimated at 9,500 ft, on both engines, approximately 20,000 ft.

## Waco on Floats

**Model CPF Waco passes D. of C. tests in airplane on Ede floats**

RECENTLY Waco's chief test pilot, John Livingston, brought a new float plane for testing on Ede floats. The job was finished at the College Point plant and after test flying at North Beach Airport, the Department of Commerce granted an A.T.C. for the CPF as a two-seat airplane. It was licensed at a gross weight of 2,800 lb. The top speed averaged 154.5 m.p.h. at 2,400 r.p.m., cruising 137 m.p.h. at 2,100 r.p.m. With full load, take off averaged sixteen seconds.

The ship is a standard open cockpit layout, proved with a Wright R-508 E engine of 250 hp. The floats are the new Model Ede 45 2800. They follow usual construction and general design pattern, but they have been cleaned up a bit, and the van between the floats of the main step has been made a little deeper. Standard water rubber equipment is fixed. Maneuverability on the water is reported to be excellent.

## Foreign Builders

**Finland King's Cup notes and a few oddities**

THE Festival Cup is a popular standard type for touring light aircraft. One of these machines, specially fitted with a 200 hp Gypsy VI, won the Söderberg Trophy in the King's Cup race. It is actually a low-wing, three-seater, cabin monoplane with a cruising speed of something over 180 m.p.h. It has a fixed landing gear, well streamlined.

One of the more unusual sights at the finals of the King's Cup race was the TRK, a machine designed and built by the students of the Delftland Technical school. It was a low-wing cabin monoplane with a wing design very similar to that of the Comet which won the MacRobertson race last year. It is fitted with a Gypsy Major engine.

A modification of the standard cabin type "Personal Gulf" has been turned out for delivery to one of the Indian Princes of Jaipur. Instead of the usual closed cockpit arrangement, two tandem open cockpits are provided. Power plant is a standard Gypsy VI.

A new plane: Waco's CPF proved with a Wright R-508 E engine of 250 hp. Top speed is better than 150 m.p.h.

Although the British D118E four-engine biplane has been developed previously, an accompanying illustration shows the latest type (4-2000 hp Gypsy VI engines) as used by Imperial Airways on the London-Hullmouth and London-Birmingham services. Of particular note is the long tapered nose, characteristic of all late models of this machine.

A curious looking amphibian has appeared recently in France, the Arriville-Freemont Mitrail. It is a high wing single biplane type with two Gypsy Major engines mounted under the trailing edge of the upper wing. Most unusual feature is the mounting of the landing gear. The wheels appear to be set into a pair of short-wing units which act as rudders on the water. For ground landings, the unit and wheel combination is lowered so that the wheels come well below the hull. For water use the whole arrangement is raised to act as a pair of tail-booms. Landing gear doors are used along the trailing edge only in conjunction with a relatively wide flap. Although the machine is rather awkward looking, nothing is known in the way of characteristics or performance. Interest in Germany tends to con-

centrate toward low-powered gliders. Among most recent examples is the RG 154, a light single-place type which in general outline suggests the Curtiss-Wright Ju of 1932. Power plant is a two-cylinder horizontal opposed air-cooled engine. Wings are not tapered, are markedly swept back.

Most interesting of the German power gliders is the Hanser-Vögelner machine powered machine. It has the appearance of a normal airplane except for a streamlined nose which extends out of the forward fuselage as a pusher. Most unusual feature is the propeller in driven through a variable left drive by foot pedals operated by the pilot and, once the machine is in the air (usually after being towed off or launched by shock cord) the pilot can obtain a considerable amount of thrust at the propeller. A number of flights from level ground have been made. The longest reported so far covered some 700 ft. Not very spectacular, of course, but so far as is known, the first flights which have been made by human power. The practical value of the experiment is, however, open to some question.

British designer, the Dr. Richard D118E used by Imperial Airways.

# The Maintenance Notebook

## Cold Weather Maintenance

**C. M. Bellin, superintendent of maintenance for National Airways, Inc., discusses some of the problems of winter operations under sub-Arctic conditions**

OPERATING an airplane in the triangular area, Russia-Bangor-Manitowish, particularly in the dead of winter, presents a number of very highly specialized maintenance and operating problems. Experience gained in operating a fleet of Stearns Model Tri since 1933 has yielded a number of hints on cold weather maintenance that may serve as a guide to others facing similar circumstances.

The main problem breaks down into three general subdivisions. The first concerns the design of suitable accessories and fixtures for preheating engines for starting purposes. The second has to do with the maintaining of normal operating temperatures on flight, both around the engine and in the cabin. The third deals with the expert maintenance problems, particularly with regard to landings in icy areas and the upkeep of airplanes.

### Starting cold engines

Number one problem, of course, is the starting of engines after overnight lay-up in temperatures as low as 30 deg. F. below zero. For as experience shows frequency of subzero in flight, it is necessary, for economy, that a minimum number of employees be kept at each station, and it is therefore desirable to make preheating equipment as simple and as easily operable as possible. It is highly undesirable to depend on a preheater outside of the engine. This usually requires labor that is not readily available, and also takes the oil to possible contamination from dirt. It also introduces a "human element" problem, for personnel occasionally had to put back plugs, rings or to replace safety wires. Although it seems best to keep up the oil in the engine. At the same time all the major parts warm up in or near operating temperature. It has therefore been found advisable to design a hood similar to a regular engine cover, fitting tightly all around, so arranged that incoming heat is directed where it is needed most. For preheating engines the induction system and the main raw suction of the engine are the critical spots. By using a Type 685A plunger's

plug connected to a sheet metal telescoping tube attached to the engine cover, as illustrated, a preheating engine can be brought up to normal operating temperature in from 20 to 30 minutes.

### Keeping engines warm

Once an engine has been started in extremely cold weather, however, there is no assurance that it will stay up at proper operating temperature. If it is very cold, the chance is that it won't. Under such conditions an amount of running on the ground will bring up full throttle power output. Just make it to add to the usual layout of oil-burners and tanks. Ordinary "Y" and "Z" vent stack" proper board pins have been found superior and recommended for this purpose.

This material is cut to proper shape, wrapped around the tank or oil-line, then sealed on the outside with water glass and powdered asbestos. In addition it is usually necessary to reduce the amount of cooling on the cylinders themselves. This can best be done by keeping a part of the cylinder in a short metal jacket as shown in one of the accompanying pictures. The width of the jacket may be varied to suit the temperature conditions encountered and

it may also have a few holes punched in it to permit a forced circulation of air. For temperatures below 20 deg. F. and 50 deg. below zero, the jacket 2 in. wide with a 1½ in. opening at the back was found to be ideal. Two ¼ in. holes were punched in front.

Keeping cylinder temperatures up by means of the jacket is important not only to maintain full engine power during flight (a forced loss of power has been noticed where cylinder temperatures have been allowed to get excessively low) but also to make full power immediately available in cases where throttles must be opened suddenly at the end of an approach glide to correct for underboom or air speed drift. Some trouble was encountered from both these sources before the jackets were applied, but after jacking, planes could be flown without trouble at temperatures as low as 55 deg. below zero.

So far, engines with short crank fly-jackets have been operated for a total of over 4,000 hours. It was expected that overhead would displace and prevent, several cylinders, but none, as other trouble. Surprisingly enough, however, it was found that some of these problems existed, and that the actual wear on cylinders was less than that usually encountered under normal conditions. The only point where attention was required was in the oil oil pump drive gear. The need of replacing this gear at frequent intervals, however, is probably much less than the sum total of the cost of operation under the former operating plan and is, therefore,

Engine covers, shown and plunger's plug set up for preheating the engine of a Stearns proved 6800s of an existing machine on National Airways.

caused wind worth accounting. One surprising thing noticed in overhead was the lack of clouds in the southeast. In several angles the usual heavy ends of oil were totally lacking and the engine could be maintained for a new runway period without the usual engine starting process. Taken as the whole, cold weather operating under controlled conditions, appears easier on engines than several operations at higher outside temperatures.

#### Preventing engine trouble

Preventing heat for pilot and passengers and visibility for the pilot through frosty windows are other problems. With ordinary cabin heating units, temperatures inside sometimes went as low as 25 below zero, and it was necessary to make use of a new suit, a sort of superheated, to take as possible exhaust heat from one engine and transfer it into the cabin. A 5-ft. gasoline fired pipe was used for the pumped heating cir-

How cold the climate made winter operations on icy runways. Here also the heat which also is used either to heat or to push planes when on the ground.

cuit. All engines hot air baffles and transferring shafts were as reasonable so that the pipe itself may be easily accepted, and no work was made on the heater tube proper. Hot air from the stove is led into the cabin through a 2 in. diameter flexible radiator pipe along each wall under the seats. A branch pipe carries a stream of heat into the cockpit, discharging over the pilot's feet. At 30 deg. below zero or under, suit, down from very badly. Best results so far have been obtained by using a double window in the cockpit with a sealed window space between two pieces of glass. An auxiliary outlet from the heating system permits the diversion of hot air into the windshield to help clear off the ice.

The lubrication of controls and other mechanisms under low temperatures is very important. Only by applying the best grades of lubricant with great frequency can they be kept reasonably free. (Under extreme conditions, standard light cleaning compounds) may be used

to replace lubricating oils. Bright greases may also be substituted for ordinary oil grease.

#### Runways and skid chains

In winter operations it has been impossible to use ski-type landing gears because some landings must be made on runways which are regularly kept free of snow. This makes it necessary to use wheel gear on the ships, and also to maintain cleared runways on all fields. Central study has been made of preventing waste at airports, for it is an expensive operation to maintain snow runways in eight airports over a 400-mile radius. Every planning must be done with an eye toward future snowfalls because the snow which is plowed from a runway builds up along the sides and to the course of the writer the heaviest snow plow has been used to the course of the runway narrow. The original planning must provide for such a scale that any snowmelt of snowfalls

may be handled without making the landing strip too narrow for safe operations.

During these snow which melts from the banks along the runways tend to flow into the center and again re-freezing converts the landing strip into a sheet of ice. It is necessary to find some means to prevent airplanes from skidding upon landing in massive plastic ground control. It has been found very practical to comp the planes with anti-skid chains. The chains selected are simply a high grade automotive type with cross-links kept in good repair and immediately dry. Chains must be so attached that there will be always one cross-link in contact with the ice at any time. Care must be taken in bending and so look the wheels, as there is a certain to produce a skid. After long experience, pilots report that the chains are valuable, and once properly used the difference between the carrying out of a scheduled flight or complete cancellation

Skid chain device placed over the tire of the landing gear of a biplane at the airport.

Runways heating equipment carried in back of biplane's airplane plane during the winter. The heat comes from the left engine (also skid chain) and the right engine (also skid chain) and the right engine (also skid chain) and the right engine (also skid chain).

AVIATION

AVIATION  
December, 1933

## Operator's Corner

an exchange of ideas on the problems of the commercial aviation industry

**QUESTION 12:** Do you find much interest in subjects which appear in your magazine? What properties of the subjects do interest you most? Do you have any suggestions for the magazine? Have you made any attempt to get the latest information, statistics or data which is available on the basis of relative or indirect flight experience? If so, what were the results?

#### Vocation first best

**I**N 1932 we made arrangements with the Pennsylvania Military College of Chester to teach airplane flying to their students. The college is close to this nation and the students are of well-to-do class. Results were satisfactory until 1932, after that, the pattern of most students were not able to pay for school and at present only few students are active in flying. When times get better we expect at least 3 per cent of the students to start with our school.

The students' time at this college is well taken up and we had to limit the lessons to one or two short flights per week. If the weather at their days proved unsuitable, students get distracted and this together with long summer vacation which these students spend as far from military work progresses and uncertainty. Our plan was to refund 25 per cent of the tuition fee to the student, to make it interesting to them and help pay for the expenses of their flight to make it more of a business.

Our opinion is that a college student's time is so taken up with his studies during his term that it would be much better if flying instruction was given during vacation time. — FRANK MITCHELL, Senior Flying Instructor, Elmendorf School of Aviation, Elmhurst, Pa.

#### ★

**QUESTION 13:** What do you do to get the public and to your magazine? What methods do you use to get the public and to your magazine? What methods do you use to get the public and to your magazine?

#### River sports attract

**SINCE** we operate solely from the Mississippi river we have found that it is not necessary to use extraordinary means to attract interest to our location. However, as there is a continuous amount of recreational interest already in boats, locks, and dams, etc., which are located adjacent to us, we find that their presence helps to attract attention to our type of operation. So long as flying itself is very interesting to watch over the

ground public and many people, we find, are so attracted by it that they spend hour after hour, evening after evening, for weeks at a time, just watching our plane operate. — GEORGE C. DUNN, Dunham Airways, Dunham, Iowa.

#### Aerobics means attract

**T**HERE are show cases to be the best method of getting people out to the airport. It will undoubtedly get more people than any other method, provided a little publicity is put out ahead of time regarding it. However, the public soon gets tired of seeing the same planes and the same pilots doing the same things, and so it is usually necessary to vary the program considerably to hold the pilot's interest. The Aerobics show can't be a large, expensive affair, but low aerobics shows to come fairly or at a scheduled time during the afternoon will always increase the attendance at the airport.

The city council of Seattle, shortly after Boeing Field had been built, changed the name of the principal highway to the Field from the downtown

business district to "Airport Way." The name of "Airport Way" as all road signs automatically does a good bit of advertising for the field. However, we do not let it reach beyond getting people out to Boeing Field, so we have never considered it a problem. — ELMER MARSH, President, Washington Airport & Transport Corporation, Boeing Field, Seattle, Wash.

#### Prize from the sky

**W**RK kept about the best method to get the public out to the Airport is an advertiser and put on free attractions in the air and also to draw both Merchandise and cash prizes on previous to stated intervals. Here Campbell and I have had considerable publicity relative to our airport landing society by plane. We put on a demonstration at the Airport of how we shoot prizes from a plane, shooting from the air as we like "Circus Spectra" in which, in that, we have brought all prizes. The most to go over with the public. — H. M. CAMPBELL, Campbell Flying Service Inc., Williams, N. D.

#### Southern facilities limited

**W**RK advertise in local papers, generally twice per year, plus radio advertising. These windows, have made some loudspeakers but nothing really systematic due to the small amount of business we can handle at this school. Southerners have not very little for air means due to limited ground to take the proper care of viewing planes but should be a great boost to local fields. A properly located airport should draw a large amount from non-commercial aviation such as circus folk, roller skating, and band music. — FRED MITCHELL, Senior Flying Instructor, Elmendorf School of Aviation.

#### Radio is best

**W**RK have used every method, including machine gun, getting the public out to our airport. Of all the methods, we have found that the best, (see page 14, November, 1933 issue of AVIATION). A recent successful attempt was to stage a flower show at the airport. A large number of flowers exhibited there were and the attendance was excellent. — C. H. MARSH, President, Airport Industries, Grand Central Airport, Glendale, Calif.

## Pacific Overture

**China Clipper makes first flight with mail, as sister ship arrives in California. Other Pan American lines step up**

There were elaborate ceremonies under way at the Alameda, Cal., seaplane terminal on the afternoon of Nov. 22. Pan American Airways read a message of congratulation from the President and made a speech of his own, as did John Trujillo and the Governor of California. Even the Governor of Hawaii and President Generalissimo of the Philippines were heard from by radio. A crowd of 20,000 lined the shores. A band played. The departure of the first transpacific airmail was not to be lightly passed over. Finally, in the great robed of Captain Merrill and his crew of eight, the last of the 2 tons of mail cranked up to an ancient steps coach and went on board the Clipper. Soon the great Main-deck boat was moving smoothly toward a take-off that lifted it above the unfaded towers of the Golden Gate bridge just before last night.

Twenty-one hours and three minutes later Merrill roared it down to a smooth landing on Ford Island, Hawaii. Once more—lands, speeches and scored records.

The next afternoon the China Clipper had reached Midway with a dozen Pan American employees, taken aboard at Hawaii Island for Midway and Wake to deliver some of the members of the late crews who had been on duty after last May.

Three days later its crew stepped ashore for final ceremonies at Midway itself.

Forty-eight hours after the China Clipper had taken off for the Philippines, a third ship, the Philippine Clipper, arrived at San Francisco Bay. Still another was expected early in December. Company officials announced when the China Clipper turned homeward after three days in Midway, that the second flight with mail scheduled for Dec. 6 would identify go no farther than the Philippine capital. After that service will be extended through to the Portuguese island of Macao off the coast of China near Canton. Passengers will not be carried until February.

Three other developments marked the Pan American month. Oct. 29 came word that the government of New Zea-

land had approved a Pan American service from Hawaii to Auckland to start possibly late next summer.

November 15, came trouble in the form of an order from the Mexican government that "no flag very dark" American Constellation, Pan American subsidiary running from Los Angeles and El Paso to Mexico City, could substitute Mexican for American pilot personnel. Pending a compromise, the airline shut down.

November 1, it put its entire Latin American network on a 150 m.p.h. schedule basis. Douglas, Electric, 54th's approved during the past two seasons made the change possible.

## Bigger Transports

**American releases details of Douglas DC-3s.**

At the first of the Douglas DC-3 transports (also called DC-2s) entered the flight test stage at the Santa Monica factory last month, American Airlines which has ordered ten of them, released more complete description of the new transports than has been previously available. Extrinsically they will closely resemble the present DC-2 model. The wing span will be 95 ft., length 65 ft., height 17 ft. 6 in., compared with DC-2 measurements of 85 ft., 62 ft., and 16 ft. 4 in. for the corresponding dimensions. Wing arrangement, structure type, general controls will remain the same, save in one instance. The DC-3's landing gear will be 30 in. water giving, automatically, a somewhat better streamlining shape.

Missing two engines of about 1,000 hp each, speed performance will closely approximate that of the smaller ship—a top of 215 m.p.h. at 7,000 ft., a cruising speed of 190 m.p.h. at 12,000 ft., at 70 per cent power. Fully loaded the new ship will weigh 24,000 lb. against the 18,900 of the DC-2. Range—and this is important—will be 1,300 miles with the ship carrying 36 passengers as a day liner, or 1,400 miles when made up as a 46-passenger sleeper.

President Smith of American called attention to the fact that the new Dou-

## 14 out of 20 of the Country's Major Air Lines use Texaco Airplane Lubricants

Higher speeds, lighter metals, and many other factors have made new and more exacting demands on lubrication. As aviation has progressed, Texaco has worked closely with engine manufacturers and has kept pace. The result of this cooperation plus advanced refining methods have made Texaco Aviation Lubricants outstanding for their purity, stability and dependability.

The performance of Texaco Aviation Oils is verified by transport officials, who, on their own teststands and by actual performance on the line, have proved the low carbon content, resistance to oxidation, and uniformity of these products. A Texaco Aviation Representative who has specialized in aviation equipment is ready to cooperate on all lubrication problems.

Boeing, which will cost more than \$1,700,000 with spares, complete a \$4,500,000 equipment expenditure started two years ago by the airline.

Other equipment programs announced last month included the purchase of complete two-way radios by Chicago and Southern and the mounting of de-ice and constant speed propellers on the entire Northwest fleet at Eastern on the Chicago-Seattle run.

## KLM Report

**Schedule keeping on the long Amsterdam-Batavia run.**

BECAUSE the American aviation industry likes to think of the aggressive Royal Dutch Airlines (K.L.M.), which have long used American engines and for the last half year flown their principal schedules in Douglas transports, as the most strictly Americanized airline in Europe, the report on this summer's operations of its Amsterdam-Batavia service holds special interest.

June 1, the new Douglas schedule of five and a half days replaced former nine-day winter and eight-day summer services. On July 1 departures were put on a two-week basis in place of the former weekly frequency. From early August to Oct. 1 and a single trip failed to cover the 8,000 mile trip on schedule.

Last factors fell due to the doubled service but by a remarkably small amount. During July, August and September, 82.7 per cent of scheduled service was completed (82.8 per cent in 1934), 70.2 per cent on-board was utilized (77.8 per cent in 1934).

## Findings

**D. of C. reports on two recent airline crashes.**

"After the probable cause of this accident was failure of the pilot to maintain proper control of the aircraft while descending through fog," is the only conclusion from evidence available to the crash board which investigated the loss of the Western Air Express Boeing 247-D at

Barstow on Sept. 1, 1933. Only crew and mail were aboard at the time. The ship was being landed from Barstow (where weather conditions were bad) to Soquel, Cal., to pick up passengers for Salt Lake City.

Error on the part of the pilot in judging his altitude or his distance from the airport or both caused the accident to a U. S. 247-D transport 10 miles north-west of Chicope (Wyo.) on the early morning of Oct. 2, 1934, according to official crash board findings. No evidence of mechanical failure could be found. The ship crashed the top of a small hill in normal flying attitude—wheels up, engine at cruising speed—crashed against a hillside 1,100 ft. away. There are some grounds to suspect that the pilot either miscalculated his altitude, or that the setting was so false, so an additional 1,000 ft. of altitude at the point of the accident would have put the ship in the proper position for a normal power glide to the airport for a landing. The pilot was known to have been flying an instrument at the time of the crash. It is possible also that he misinterpreted the vacuum position report, and started losing altitude faster than his actual position warranted.

## New Beam Rulings

**Bureau of Air Commerce takes steps to prevent blind collisions.**

ON Nov. 1 the Bureau of Air Commerce issued an amendment which put into effect—Notice in all pilots and operators: 1. As a precautionary measure and until the present tentative regulations are approved, no pilot shall enter an uncontrolled instrument flight through clouds within 25 miles of an airport or enroute airport. 2. Flights under the hood may be made only with safety pilot who has full visibility. 3. The only authorized flying under this ruling are those of scheduled airlines operating under letters of authority.

Independent private flyers, local operators, and radio amateurs from all over the country were present. Vital explained. Narrowly missed collisions between airplanes and other aircraft automatically using the same radio because had worried line operators and Bureau officials for months. The Nov. 1 ruling would be modified at a conference in Washington one day later. It had simply been a means of clearing the decks for discussion.

On Nov. 15 another "suspension" under the enforcement which retained the above but added to emergency aircraft with two-way radio capable of a 25 mile range, and manned by personnel who have demonstrated their use. However, when pilots of such aircraft take advantage of such exceptions they must communicate if possible with all

## Traffic

**Latest available statistics from the Bureau of Air Commerce and the Post Office Department—Domestic airlines only.**

Department of Commerce stations along the route, most subject to the Bureau investigation and at least one airline a flight plan at these points of departure to be relayed ahead to destination. Such plan not to be deviated from, except in emergency.

Reports on the Washington traffic control conference have not yet been published. A preliminary report is expected.

Push for a prominent manufacturer of transport airplanes, the largest and latest AIRWHEEL, with Goodyear multiple disc hydraulic brakes, is good beside our machine and wheel too.

## Now comes a still bigger AIRWHEEL\*

AS MASTERY of the skyways progresses with larger ships, Goodyear keeps pace by providing equipment essential to comfortable landings and take-offs.

Thus the largest Airwheel yet needed was requested by one of America's largest makers of airliners. And to give pilots dependable ground control, Goodyear multiple disc hydraulic brakes were specified also.

This still bigger Airwheel stands 45 inches high and its cross section is 20 inches. It weighs 125 pounds. At 35 pounds air pressure it is rated to carry a load of six tons.

Completely, competently, Goodyear serves the tire, wheel and brake needs of aviation. Try Goodyear first—just write Aeronautics Department, Akron, O., or Los Angeles, Cal.

\*IF IT ISN'T A GOODYEAR IT ISN'T AN AIRWHEEL AIRWHEEL is Goodyear's multiple, engineered in the U. S. A. and brought out the world, and is used to denote that Goodyear is the exclusive maker of AIRWHEELS.

early in December. Final findings must await the results of witness studies of the sub committee of operations, plans and private owners appeared Nov. 12.

## Locked Controls

**Army Board finds no structural or engine failure in 299 crash.**

No evidence of failure of structure or of control surfaces, nor failure nor malfunctioning of engines or propellers was found by a Wright Field crash board investigating the loss of the *Boeing 299* bomber at Dayton on Oct. 30. All testimony of observers and survivors led to the conclusion that "the direct cause of the crash was the locked condition of the rudder and elevator control controls (primarily the latter) which made it impossible to control the airplane." Why they were not unlocked will never be known, for Major F. F. Hill, the pilot, died in the wreckage. Possibly the lock had never been disengaged—possibly the unlocking handle had been jammed—possibly, possibly the handle had been fully depressed, and for some reason the locking pins were not fully disengaged. One guess is probably as good as another. If underlying causes were discussed, the results were tragically plain. In the language of the official report "299 . . . on day authorized test flight, took off, immediately assumed an abnormal steep climbing attitude, continued in this attitude until it stalled at approximately 300 ft altitude, and then crashed, power on, on the runway, and immediately caught fire."

Major Hill probably did not survive the impact. Leslie R. Tower, longtime *Boeing* test pilot, recovered in ruins and burns from which he died three weeks later. Harrow work on the part of field personnel saved the lives of the others of the crew, co-pilot Lt. Donald L. Pratt, flight test observer John H. Clumey, and mechanic Mark B. Roopler.

The loss of 299 surrounded the field of competitors for new Army bombers (for which bids were opened in Aug. 21) down to the Douglas and Martin entries.

## Ten Months Notice

**National Air Race program for 1936 released. Prize money boosted to \$60,000. 1935 Eastern Trophy troubles.**

TOTAL prize money for the 1936 National Air Races at Cleveland will be 20 per cent higher than it was this year. Special licenses will be offered for new National Air Race routes in the Thompson, Fordor, Groves and 375 cc in. races. The 200 cc in. class race last has been replaced with a race for planes equipped with engines of 286

**1,400 MILE SLEEPER**

shows the *Boeing 299*, winner of the Douglas *BOV*. An artist's drawing of the new 35-engine *Boeing 299*—15 engines each driving two sets of *Boeing* *Boeing*. American Airlines has ordered two.

cc or under. The handicap race for women will carry a top speed limit of 175 mph in place of this year's 150 mph and a new qualifying speed of 330 mph—each were the high spots of the reform last month from the Cleveland sponsors about next year's National Air Races to be held Sept. 3, 4, 5 and 6.

Most significant of all was the fact that the release of such information at this time marked a new departure. In the past it rarely appeared before late spring or early summer. More prize money, location for next year's, an earlier start of classes and qualification should do much toward insuring better race performances.

Prize money posted for the principal events—Thompson \$20,000; Fordor, \$12,500; Groves (\$30 cc in.) \$12,000, 375 cc in., \$9,000, 286 cc in., \$2,400. Women's A, T, C, \$1,500; Men's A, T, C, \$1,000, Provisional Competition, \$600.

The N.A.A. has announced a final settlement of a situation arising from its error in handicapping of this year's Amelia Earhart Trophy Race.

Immediately after the finish of the race Mrs. Hilda Beaul was named the winner of the race, with Mrs. Edith Beaul in second place by a fraction of a second. Soon after, at error in the computation of Mrs. Beaul's starting time was discovered and the position of the two leaders reversed. Mrs. Beaul should be credited with winning the race and be awarded the trophy but should receive only second money, first money to go to Mrs. Beaul.

## Los Angeles Show

**Details released on West Coast aircraft display.**

More facts are now available on the National Pacific Aircraft and Boat Show beyond the bare announcement of a month ago. The date has been definitely set, Feb. 1-5. The location will be the large Van Nuys Auditorium, modernized 110,000 sq ft display building in the center of Los Angeles residential district. The same building was recently the site of Los Angeles Auto Show and National Fishing Show. It is the second largest convention building in the United States.

The Henderson Brothers, Cliff and Phil, who manage the National Air Races, will also manage the coming show for the California Air Industries Association, which consists of leading Southern California manufacturers, distributors and operators and is headed by Harry H. Winter, vice-president and general manager of the Douglas Aircraft Company. The Association's show committee consists of Parker S. Stoddard of Pacific Airways, Carl B. Spitzer of Lockheed, and Walker P. Balderton of the Pacific Scientific Company.

Active support has been promised by the Los Angeles Chamber of Commerce, Junior Chamber of Commerce, and the local Chapter of the N.A.A. The exhibition has been announced by the Aero-Naval Club of Commerce.

An extensive list of exhibitors is expected. The Henderson's statement that early reactions promise the largest show since pre-depression days.

## C.H.Q. for Miami Meet

**Big Air Corps force to feature this year's southern classic.**

AL WILLIAMS, Chief Sales, The Three Aces, who call themselves the Three Aces of the South, the program for the 1935 Miami Masters, promises as many headlines as were present at the fall's national affair at Cleveland's municipal airport.

More important, the eastern arm of the C. H. Q. Air Force will finish two weeks of maneuvers over Florida by a visit to the races scheduled for Dec. 12-13-14. Some 75 National Guard planes from nearby states are also expected. Grandstand accommodations for 15,000 have been prepared.

The three-day program features a wide variety of races. Air C. formed ships, four five-day races with dis-

placement, significant only, and a women's landing race. Prize money totals \$5,000.

## Up Balloon

**Captains Stevens and Anderson set new altitude record.**

At 10 a.m. Nov. 10, the astrophysicist attached to the Air Corps-National Geographic expedition informed Capt. A. W. Stevens and David A. Anderson that their Indian "two member" was for another good enough for a stratosphere flight was at an end. Three hundred convalescents from Fort Meade were assembled to the level-like valley at Eagle Crag, S. D., to help with the inflation, that was started that evening. By midnight the ship's counter-million cut of helium had been piped into the huge envelope. A short trip appeared in the

bottom panels but was successfully repaired.

By 7 a.m. all was ready. The two captains dressed in heavy flying suits, football headgear and harness for quick-attach parachutes strapped into the tiny semi-metal globe. Thousands of spectators had gathered to watch the ascent. The ship climbed swiftly, 800 ft light, cleared the high volcanic walls of the valley by 90 ft. At 15,000 ft the ascent was stopped until a number of instruments could be reset on levels below the ground. Then the balloons were sealed and the climb was resumed. At 31 a.m. the objective height of 23,000 ft was reached at a point over the Missouri River in northern Nebraska.

Readings sent on steadily. The effects of great altitude upon photography, radio, cosmic rays, space distribution, atmospheric composition, and the general distribution of sunlight were studied. For more than an hour the stratosphere, now a huge spherical bag of 2,700,000 cu ft, floated, remained at its new record height.

Then slowly it began its long descent. At 25,000 ft, the crew began dropping ballast to hold the rate of descent to 500 ft per minute. At 14,000 ft, that rate was cut to 150 ft. per minute, then to 50. A flying rope went over. A low line of the ground Capt. Stevens pulled the rope over. The goods, including the pilot, then made a slow quarter roll onto its side. No damage had been injured.

Officials of the National Geographic Society which had sponsored the flight were jubilant. Yet once during the flight had the slightest flaw appeared in the Goodyear-rubberized Wellington-bears fabric. Not so measured had been lost or damaged. The new N. A. approved altitude of 23,200, best the former unofficial Soviet mark of 23,175 by a small margin, and was over 12,000 ft. higher than the P. A. I. record held by Seale and Fordy.

## Two Are Missing

**Kingsford-Smith and Ellsworth disappear on record-seeking flight.**

Last month two great pioneers in aviation lost touch with civilization under circumstances to cause the greatest concern for their safety.

Both had long records of aeronautical achievement behind them. Both a few which bolstered the world's hope, but both missing before under somewhat similar circumstances.

For Charles Kingsford-Smith held more trans-oceanic records than any other flier. He had been first to fly from California to Australia, first to enter the remote territory. He had been second to make the southern crossing to the Atlantic. He had landed Fokker im-

AVIATION  
December, 1935

A NEW 300,000 C.U.F.T.

of helium was put into the spherical envelope. It before taking off its new altitude record. At 10,000 ft. it took the great bag of Goodyear-rubberized Wellington-bears fabric and in a matter of 15 minutes it was at 23,200 ft.

CONSTANT SPEED  
**Control**

FOR ALL FLIGHT CONDITIONS

On September 4th, 1933, James R. Wedell set a world's land plane speed record at 304.98 m.p.h. using a Hamilton Standard controllable pitch propeller. On September 13, 1935, Howard Hughes restored world leadership to America with a speed of 352.46 m. p. h.  
using Hamilton Standard's latest development—

The Constant Speed Propeller.

## No difference to FAFNIRS

The new twin-engine Lockheed Electra and the single-engine Orion, of the fleet operated by Northwest Airlines, Inc., are Fafnir-equipped Eclair bearings, sleeve bearings, roller bearings, control columns and cable pulleys feel "substantially the same" as when new, after many hundreds of hours of flying time," according to Mr. K. R. Ferguson, General Traffic Manager of this northern transcontinental air route connecting Chicago with Seattle via Twin Cities and Spokane. "The use of these ball bearings has considerably reduced greasing and maintenance problems as well as repairs to these parts."

"In the case of one route through the northern part of States, our equipment is subjected to extremes of temperatures ranging from more than 100° F. in

summer to as low as 40° below zero in winter. In spite of these extremes, these Fafnir Ball Bearing-equipped controls function perfectly under all conditions," adds Mr. Ferguson.

The experience of the Northwest Airlines has been duplicated by many other leading airline companies. Fafnir was the first to develop ball bearings for control surfaces, and their stored-up experience is available today, to enable you to operate with friction losses reduced to a minimum. Capable the Fafnir Bearing Company, Aircraft Division, New Britain, Conn. . . . Atlanta . . . Chicago . . . Cleveland . . . Dallas . . . Detroit . . . Kansas City . . . Los Angeles . . . New York . . . Philadelphia . . .

Fafnir's "Double Sealer" BALL BEARING FOR AIRCRAFT, showing the exclusive oil seal which keeps dirt out and grease in for the bearing. It has no holes.

# FAFNIR BALL BEARINGS

motor the Southern Cross he had circled the globe. He had set a solo record from Australia to London.

Now 4, he left London with a companion, J. T. Pennington, in his Lockheed, Lady Southern Cross, in an attempt to lower the London-Australia record. The two made perfect time to Baghdad, then to Alabaha. Off the coast of the Malay Peninsula they ran into a severe typhoon. C. J. Morrow, himself among the solo record, caught a glimpse of the Lockheed battling through the storm a mere 200 ft. above the water some 150 miles from the coast.

No trace has since been found. Lincoln Ellsworth had been with Amundsen on the first attempt to explore the Arctic by plane in 1925, and again in the following year on the first over-pole flight to the North Pole in the Norge. Last year he had led an motorized expedition to the Antarctic, proposing to fly across a wide stretch of unexplored territory there.

Last month his lone ship, the Wynd Earp, eased through the pack ice to find a take-off into port for his Northrop Gemini on December 24th, 2,400 miles from Ellsworth's old base at Little America. Ellsworth and his Canadian pilot, Herbert Heibel Kreson, proposed to fly to Little America and walk there and their base ship under command of Sir Robert Wilkins would off to pick them up.

Twice during the third week in November they took off but were forced back, once by a fuel pipe leak, once by bad weather.

On Nov. 23, they started again. Five eight hours radio reports told of good progress. At that point the signals became quiet. Ellsworth, then stopped. The two ships could not tell whether the radio signal had faded or the ship had disappeared. No word had been heard from the explorers days after the take-off, when this issue of AVIATION went to press.

## Soviet Heights

Russian Air hosts F.A.I. airplane altitude mark

On Nov. 21, a single-engine, single-seat biplane took off from Moscow's airport carrying 31-year-old Vladimir Kozlovskiy, once a soldier and aviator, now test pilot for the Soviet Air Force.

A few minutes more than an hour later the ship disappeared, spiraling in toward a dead stall landing. Pilot Kozlovskiy clanked safely from the cockpit perched out of his lone oak and bulky flying suit.

The next day Soviet press announced a new feat. A check of Kozlovskiy's logbook revealed he had reached 42,033 ft., 464 ft. higher than Commander Renato Donati's current F.A.I. record.

But Donati's record of 41 stands in most

countries. Russia has never become a member of the Fédération Aéronautique Internationale.

## Financial

United Airlines reports a profit, American a loss. General Motors sells TWA control.

✦ **UNITED AIRLINES**, for the quarter ended Sept. 30 reported a net income of \$284,886, equivalent to 22.2 cents a share on outstanding stock. For the same quarter ended Sept. 30 a net loss of \$15,564 was shown.

✦ Working control of TWA, Inc., transferred last month from General Motors to Lubman Brothers and Atlas Corporation, the country's largest investment

firm. The latter firm purchased the entire General Motors block of \$1,254 shares, 13 per cent of those outstanding.

✦ Tuesday hearings on allegations that the restoration contract filed for a proposed case of **BELLAROSA AIRCRAFT** stock included "various statements of material fact" and "various to state material fact" and that Michael J. Bellarosa, head of a New York stock exchange firm had been manipulating Bellarosa stock on the New York Curb Exchange, the S.E.C. has today way a stop order against the new issue.

✦ **AMERICAN AIRLINES**, Inc. reported a net loss of \$20,545 for the nine months ended Sept. 30.

**Operating Results:**  
Operating income . . . . . \$1,011,000  
Operating expenses . . . . . 1,031,545  
Net loss . . . . . \$20,545

## Side Slips

By Robert R. Osborn

ICE forming on the windshield of his C-47 bi, one-engine airplane (head Edward W. Stett of Stokeland, Ill., to land today at nearby Woodville, interrupting an attempted distance record flight from Des Moines, Iowa, to Washington.)—Clipped from the Washington (D. C.) Star.

When the experts forming on the ship one is intended to find proof of getting it down in one piece.

We are glad to see Mr. Ellsworth busy in his Antarctic expedition again. We don't know him personally but from his appearance and actions he must be a very capable individual—and the fact that he is in a position to finance his own expedition gives him a great advantage, as far as giving names to new territories, mountain ranges or water passages he discovers is concerned. Ellsworth always has a good admirer of Walt Long, the famous mariner of three of the toughest towers in the old West, we heartily approve of that name for Mr. Ellsworth's supply ship, and, with Mr. Ellsworth relating the names of his own discoveries, we need have no fear that future generations will be puzzled by aerial lists of Kresy Kresy, Des Moines, and Stokeland, or Frostproof, Matron, Platoon.

As we go to press the first Martin boat is about to start as the official opening of the new Pan-American service across the Pacific, and we are told that Mr. Farley will be present to press a button just as the first ship leaves the water—

the button to start lights in all of the port offices throughout the land regarding that the air mail to the Orient has begun. Another highlight of the program will be that a vigorously kind of well will arrive beside the waiting plane to demonstrate the progress in transportation of the mail in only a few years. We do hope that someone will place a large sign on this signpost telling just what it is supposed to symbolize and demonstrate—otherwise signs of the crowd may think of it as indicating the probable method of carrying the mail in the air, but, if the present attitude toward the airlines is to continue.

In commenting on the starting of the Trans-Pacific air mail service, one writer in a Washington paper speaks on the shortcomings of the name "Gipper Ship." We quote from his article:—"For many, it may be supposed, the historical background of the acronym will be interesting. No one, I suppose, may have found the origin of the phrase 'Gipper ship.' Some authorities believe it may be linked to the expression 'go it a clip' signifying 'one fast, as a horse.' Others declare it comes, much more directly, from the word 'Gipper' meaning 'moving rapidly.'"

However, is the origin of the name seems to be in double let's return to ordinary sense to let's say that it means "To make and progress, in spite of governmental indifference." or "To go faster, with the help of a lot of horses from the engine manufacturer."

# Schools, Services, and Airports

●**ALABAMA**—Capt. John Davidson, National Guard flyer and sponsor of the Southern States Aviation Exposition, was named State Director of Aeronautics at the organization meeting of the Alabama Aviation Commission held Oct. 22 in Montgomery. Harry King also has opened a repair shop at the Birmingham airport for the past two years has taken over Captain Davidson's company.

●**ARKANSAS**—New plans of the eighth normal Arkansas Air Tour headed at Memphis on Oct. 13. They visited fields in east Arkansas and reported all in excellent condition due to CWA and KRA aid. Their visit at Portland was made the occasion for the dedication of the new airport in that city.

●**CALIFORNIA**—A survey in connection with a movement to rid Southern California airports of dangerous lighted towers, reveals that of 38 fully surveyed airports, 15 are from such towers.

Automated improvements at March airport, from WPA funds, will greatly aid in night landing field. Plans for a cross runway at Clover Field, Santa Monica, have been approved by the Department of Commerce. Paul J. Barakat, formerly with Northrop company, has been added to the teaching staff of the aeronautics department of Chaffetz Junior College. Santa Barbara officials believe that the improvements being done by Santa Barbara Airways at Goleta airport will place it in the ranks of the best privately owned airports in California. Stockton's municipal airport will receive under a temporary lease arrangement until the first of the year, after which the title of the field will be donated by the City Council.

●**COLORADO**—Lieut. Ray Wilson, formerly with the 125th Observation Squadron, Colorado National Guard, recently assigned the former Captain Wright flying field at Denver. Five ships are already kept there. The 125th Observation Squadron, commanded by Maj. Virgil H. Stone, participated in airshows held in October at Alexander Park, Colorado Springs, and at the Denver Municipal Airport.

●**CONNECTICUT**—C. De Wintchey of the Hartford Chamber of Commerce

has presented to the War Department at Washington full data concerning the suitability of the municipal airport as an Army air base. The promoters who have taken back the Moisant airport (Stratford) property on a lease-lease have announced they will close the field Dec. 13. Improvements to local airports at Meriden, Danbury and Glastonbury have been recommended to DPA. All these developments call for drainage, reinforcing, and enlargement of flying areas.

●**DELAWARE**—On Oct. 17 a fire destroyed the hangar and airplane shop of Air Service, Inc., on the Delaware Field near New Castle. Quick action by George Dena and twelve pilots loaned a plane for construction of a new hangar were assisted by R. D. Morgan, president of Air Service, Inc.

●**FLORIDA**—R. Y. Waters was re-elected president of Greater Miami Airport Association for the seventh con-

secutive time on Oct. 24. Dr. Gust Grilly, director of Aeronautics at Miami, and Louis Marquis, director of civil aviation in Tampa, stopped off in Miami before returning to their own countries, as the recipients of that year of the United States Daring Air Navigation Award. Recipients of Tampa honor Jerome A. Waterman, chairman of the aviation committee of the Chamber of Commerce, on air line level recently. A discussion of National Air Defense by Maj. R. W. Cochran featured the Greater meeting of the Jacksonville Pilot Club.

●**GEORGIA**—Macon's City Council has approved the purchase of 250 acres for a new municipal airport. Work will begin at once under a federal allotment of \$207,338. Application is pending for an additional \$60,000. Aircraft and passenger service, suspended because Eastern Air Lines' new planes could not land and take off at Miller Field, will be restored to Macon as soon

A MODEL AIRPORT

made in connection of Field Project 1948 on 17 with the when the massive WPA improvements are in progress are featured. The new take-off and landing runway will be important addition to the new take-off and landing runway along the border of the city.

It is a tribute to the airplane industry that wing construction now matches the modern bridge in reliability.

NATIONAL  
PACIFIC

## AIRCRAFT & BOAT SHOW

### 1952 AVIATION PREMIERE

This leadership in the aviation and rapidly expanding market for all products and services of the aviation industry.

Participate with the Nation's outstanding aircraft and marine manufacturers in the economic, cultural and educational program of the new 1952 comprehensive show at the address of the new city that will substantially add to the public appeal. Share the benefits to be derived from the new great aviation market in which it will primarily exist. The aviation industry will be there.

The magnificent new Pacific Auditorium in the heart of downtown Los Angeles' business center provides the setting. It is admirably designed for business, social and entertainment. A 60 foot tower, 100 feet high, will be erected at the completed early value.

How manufacturers, distributors, operators and customers in every department of aviation will be in attendance. For further details, write to: California Air Industries, Inc., 1212 Broadway, Los Angeles, California. Sponsored by CALIFORNIA AIR INDUSTRIES, INC., LTD.

LOS ANGELES  
FEB. 1 TO 9

●MISSOURI—Robertson Aviation School, operating at Lambert Municipal Airport, St. Louis, has added Lewis J. W. Spencer and Walter H. Kivens to its teaching staff. The City Council of Kansas City has appropriated \$24,000 for construction of a two-story addition to the WPA building at the airport. The city of St. Joseph is moving toward the purchase of a 400 acre tract for a new airport near Peach Bottom.

●MONTANA—Both Teton Field airport at GREAT FALLS and the MISSOULA airport have had new lighting equipment installed. Clifford Hamilton, formerly of Detroit, has been placed in charge of the aviation department of the University of Illinois.

●NEBRASKA—There have been completed for a \$300,000 improvement of the OMAHA municipal airport, including runways, lighting system, a roadway, and an enlargement of the present building space. Lincoln's City Council has accepted the municipal airport's refusal to make extensive airplane noise a law violation.

●NEW HAMPSHIRE—W. R. Murphy of Manchester has signed a contract to build at the municipal airport at RABBIT. Edward H. Spooner of CLAREMONT, active in aviation since 1929, has been appointed to direct WPA projects at New Hampshire airports, specifically the improvements to be made under the \$51,236 grant to Man-

chester and the \$40,661 grant to Claremont.

●NEW JERSEY—Cooperation of the administration, headed at Newark airport, has been delayed until enough of it is finished to equip space to all airlines desiring to use it. . . . Apparatus have entered the market of additional land sought for the Newark airport at half the total of \$100,000 asked for it by the owners. . . . An air show staged at Jersey City airport as an effort to save it from being used as a site for a new stadium lost a stronger string from a place reading "Save the Jersey City Airport." The Flying Club of America and the Aeronautical Association of Illinois County have also protested. A certain reinforced asphalt surfaced runway will be installed at Newark airport as part of the \$3,000,000 WPA improvement program on which work will start in the spring. . . . A G. Norwood instructor in the Teachers High School flying section, has assumed temporary responsibility of Newark's airport next February. The airport operating company is awaiting delivery of a new Taylor Cub.

●NEW MEXICO—The Young-Smith Air Service, which recently took charge of the Albuquerque airport, has purchased a two-engine Sikorski for charter work. E. W. Brown is chief pilot.

●NEW YORK—In a demonstration of the safety of three-engine flying, 51-one airplane flies at altitude at the Boca Raton Field, Association carried 30 passengers, including the mayor of Rochester, from the municipal airport in Danbury, New York, late in October. . . . An administration building and two new hangars, to cost about \$250,000, will be added to Buffalo airport of present WPA plans carry through. Five airports in the largest at Buffalo Falls municipal airport on Oct. 26, destroying eleven planes. . . . Newark's airport, now known as Stewart Field, has been denied to the government for a military airport, with the proviso that the city may return 5 acres for a municipal hangar. John J. Sullivan has been elected president of the newly organized Syracuse Aeronautical Association. . . . Mayor W. P. Brooks of Hoboken airport, will establish his own flying school at the old Knickerbocker aviation office, Flushing airport. Joe Rank of Vermont will teach the students. . . . Delegation of the intermediate holding field and government weather station at Port Tufts airport on Oct. 7 was witnessed by more than 10,000.

●NORTH CAROLINA—The Charlotte airport was donated to military, commercial, and private aviation from New 1 to 15 because of hazards existing during the construction of a track for automobile races. An air show held

at the port in October brought scores of airplanes from nearby states as contestants for prizes awarded by the Charlotte Navy Club. Robert F. Taylor of Charlotte has been appointed captain for Eastern Air Lines on the Atlanta to Chicago run.

●OHIO—Alumni's action in raising the danger of Air Services, Inc., for \$2,000 back rent has been characterized as "arbitrary and confiscatory" by R. F. Kitzinghaus, president of the company, in a letter to stockholders. Although \$25,000 has been requested by CWA and FERA on improvements to LANA's municipal airport, the Department of Commerce has ruled that airways cannot use the port until hand-surfaced runways, proper lights, water and hangars are provided. WPA aid is provided by the fact that the city has only a five-year lease on the site. . . . An air show presented by the Aero-Naval Association and Chamber of Commerce at Hamilton airport in October drew 15,000 spectators. Tom Rankin and Harold Neumann, vice among the performers. . . . Dedication of the new aerodrome situated at Wright Field, Dayton, with special honors to the Wright brothers, is planned for Dec. 17, anniversary of their first flight. . . . Sandberg Aeronautical Corporation, operating at the Cleveland Municipal Airport, is now Census dealer for all territory east of Indiana.

●OKLAHOMA—Now that Oklahoma City's \$435,000 application for improvements at the municipal airport has had Washington's approval, Bill Bradley, manager late in October. . . . As federal officials plan to send the west side for student and army operations, entered the main runway to a full mile, added night landing lights, and electrical lighting quarters for the Army Air Reserve unit and a combination hangar-laboratory for Wiley Post Aircraft Corporation.

●OREGON—Tex Bacon has been elected regional vice-president of the National Association of State Aviation Officials for Oregon, Washington and Idaho. . . . The SWAN Island airport has failed to pass the Department of Commerce requirements for heavier air traffic, the department recommending that a new site be contacted. Meanwhile, a commission, headed by Harry K. Coffey, and including 125 members of the Aero Club of Oregon, has been formed to conduct a survey for an airport to cost \$1,000,000 to \$3,000,000. It covers a plot of land 15 miles southeast of Reddy River and 3 miles northwest of Gresham for the new site. . . . F. F. Holmes, director WPA project, has improved Main Island as the logical site for an airport for Grays Harbor County.

(A McGraw-Hill Publication)

## Just published A simple, practical text book on airplane performance and stability calculations

This book presents a concise treatment of the aerodynamics of airplanes, covering the basic principles of airplane flight, and emphasizing reliable tabulated data and their use in making calculations of airplane performance and stability.

## TECHNICAL AERODYNAMICS

By KAREL D. WOOD  
Assistant Professor at University of Tennessee, Craigville, Tennessee.  
Continuum Mechanics, American Institute of Physics  
136 pages, 6 x 9, 277 illustrations, \$5.50

This book is unique in a class, concise manner and with the emphasis on useful data that will be appreciated by the practical engineer and the student of design.

One of the foremost objectives is to emphasize methods of calculation and the principles on which they are based, and methods of using them for those problems of performance and stability of an airplane without special word search notes.

The book is up to date, covering practically all developments of aerodynamics up to mid-1950s. It is the latest of printing. Among the especially useful items for the designer and researcher, it includes, etc.

- recent developments in aerodynamic theory
- simple parametric drag estimates, with comprehensive tables of data
- basic propeller charts and data
- charts for quick estimates of performance
- data and simple comparisons for stability
- latest NACA data on hulls and floats
- complete data on current commercial airplanes and engines.

"It is needless for us to say that the book speaks to us directly in the quantity ordered by the private libraries of aviation students at our general aviation schools for its usefulness."—Paul E. Harkness, University of California, Berkeley

\* Election of J. D. Bows as executive vice-president and general manager of Berry Brothers, following the resignation of T. J. Campbell, former president, was announced at a recent meeting of the board of directors. Mr. Bows has heretofore served as assistant general manager and controller of the company.

• **United Aircraft Corporation of East Hartford, Conn.**, elected **HARRY G. FROSTMAN** to its board of directors. Mr. Frostman has been president of Wyman-Gordon Company of Worcester, Mass., since 1935, and was previously connected with Trucon Iron Company and American Steel & Wire Company. He is also president of the Worcester Telegram Publishing Company, and serves on the directorate of many New England organizations.

• Alfred A. Gussner has taken two months' leave of absence from his post as chief engineer of the military and transport division of Fiedrich Aircraft Corporation in order to act as a temporary consulting agency with Junkers in Germany. Mr. Gussner was for many years chief engineer of Fiedrich Aircraft Corporation.

\* On Nov. 25 Dr. STEPHEN J. ZAMM lectured before the Royal Aeronautical Society in London on sound-proofing of aircraft. The speaker, whose work on noise abatement is well-known in the industry here, spoke on the development of sound proofing and its technical aspects.

\* United Air Lines officials have announced the election of Paul A. Wagner to the presidency of United Airports Company of California, to serve as general manager of United Air Terminal. Mr. Wright was previously stationed in Chicago where he was secretary of United Air Lines Transport Corporation and assistant to President W. A. Patterson.

\* The Lithuanian Government has conferred the Order of Vytautas the Great on PAULI WAKARUS, Wisconsin, dyer who attempted a New York-to-Lithuania flight. More than 100 streets in Lithuanian towns have been named after him.

\* Seven armed forces who have recently been awarded medals of honor by President Roosevelt for heroic achievements during the past year are

GREGORY S. DARNELL, Kennesaw City.  
EDWARD A. BELLANT, Hollywood.  
LEWIS S. TURNER, Fort Worth. JAMES  
H. CARMICHAEL, Jr., Detroit. WILLIAM  
LUTHER P. McFAR, Harrisburg.  
ROY H. WATSON, Portland. GARRETT  
TALAN, Seattle.

• As of Nov. 1, E. S. Krieger & Sons, manufacturers of musical instruments and aeronautical compasses at Brookline, Mass., became E. S. Richter & Sons, Inc. The company continues under the same management, with E. C. Krieger as president and treasurer.

\* The War Department has presented the Distinguished Flying Cross to Flying Cadet Pearson H. MacDore for

harmless displayed in June, 1915. With his airplane in flames, Cadet MacDuff remained at the controls to maneuver it in such manner that his passengers were enabled to make successful parachute jumps to safety.

\* The crash last month at Wright Field which destroyed the Boeing 298 bomber, cost aviation two splendid flyers.  
 \* Purser P. Hunt had been commissioned a Major in the Air Corps but a few months before 41 years ago in Massachusetts he had graduated from Brown University in 1946 and married the Army Signal Corps Air Service during the World War.

Lincoln Taylor, chief test pilot for Boeing Aircraft, was regarded as one of the front-ranking men of his profession. A native of Macon, he entered the Air Service in 1923, after three years at the University of Washington. Graduating from Kelly field in 1926 he entered the employ of the Boeing company, becoming chief test pilot two years later at the age of 24.

## B17L OVER ETHIOPIA » »

*and even Haile Selassie goes Airminded!*

According to reports from Addis Ababa the Lion of Judah became airminded when he saw the performance of a B17L Beechcraft. He was filled with admiration and saw at the wings of the Beechcraft cast a fleeting shadow over the Eucalyptus groves of Ethiopia's capital city.

Stories of the exploits of this Beechcraft outmaneuvering and out-distancing the trained Italian air forces—bringing back pictures and news from inside the lines—have been front page news in the nation's large dailies for the past month.

The graceful lines, the spectacular and near unnecessary performance of the Beechcraft has

captured the fancy of the people of all nations.

But what is of even greater importance is the relatively small group of aviation experts—engineers and prominent pilots—who have found the Beechcraft structurally sound and aerodynamically correct. They know that the Beechcraft will fly faster and carry larger useful loads.

Beechcraft has clipped hours off the air distance between cities—has reduced the cost of air travel to that of an automobile—has established an enviable record of all around safety and stability.

Beechcraft offers business executives a travel convenience never before dreamed of.

Drop in a line for full specifications and performance data.

# *Confidence starts with starting ...when it's Eclipse Starting!*

**N**OTHING associated with flying builds more confidence than a sure, swift start. Airline passengers and air service students alike enjoy hearing the engines roar into life promptly and without reluctance. Confidence starts with starting!

Eclipse Engine Starters handle this critical job for every American transport airline, for the Army, Navy and Marine Corps, and for most civilian aircraft. Whatever the type of Eclipse Starter employed—whether Hand Inertia, Direct Cranking, Electric, Combination Hand and Electric Inertia, Hand Turning Gears with and without Integral Booster Magneto, or Air Injection—Eclipse Starter equipment has the vital requirement of absolute reliability.

If the engine is in starting condition, Eclipse will start it.

**ECLIPSE AVIATION CORPORATION**  
EAST ORANGE, N. J.

*(Subsidiary of Bendix Aviation Corporation)*

*A typical type of hand turning gear.*

*A direct cranking electric starter with auxiliary hand crank for emergencies.*

*A combination hand and electric inertia starter with solenoid starting relay attached.*
